MACROECONOMIC IMPACT OF REMITTANCES ON OUTPUT GROWTH: EVIDENCE FROM TURKEY

Aysıt Tansel and Pınar Yaşar

Working Paper 586

May 2011

This article is based on Pınar Yaşar’s MA thesis (Yaşar 2005) prepared under the supervision of Aysıt Tansel at the Department of Economics, Middle East Technical University. An earlier version of this paper is presented at the Turkish Economic Association (TEK) International Conference, 11-13 September, 2006, Ankara. We appreciate the able research assistance of Eda Gülsen. We would like to thank two anonymous referees of Migration Letters for valuable comments. Any errors are our own.

Abstract

This study estimates a Keynesian simultaneous, dynamic macroeconometric model to investigate the impact of remittances on key macro variables such as consumption, investment, imports and income in Turkey. The estimated impact and dynamic multipliers indicate that the impact of remittances on consumption, imports and income are all positive and reduce gradually while that on investment wears out in the second year. The impact multiplier for income implies a substantial increase in income due to remittances through the multiplier process. The remittances-induced output growth rate is highest during the early 1970s and the early 1980s, but negligible during the other years.

ملخص

تعطي هذه الدراسة تقديرات لأحد نماذج تأثير التحويلات على الاقتصاد الكلي المتزامن بهدف دراسة تأثير التحويلات على المتغيرات الكلية الأساسية في تركيا مثل الاستثمار والاستهلاك والواردات والدخل. يشير التأثير المقدر للمضاعفات إلى أن تأثير التحويلات كان إيجابياً على كل من الاستهلاك والواردات والدخل، بينما أثرها على الاستثمار ضئيل خلال العام الثاني. يشير الأثر المضاعف للدخل إلى زيادة حقيقية في الدخل بسبب التحويلات من خلال عملية التضاعف، وقد بلغ معدل نمو الإنتاج المحفز بالتحويلات أعلى درجاته في نهاية الستينيات وأوائل الثمانينيات وأكثر الأعوام الأخرى.
1. Introduction
Migration flows have become one of the most important features of Western European countries after the Second World War. While Western European countries undertook several measures, such as bilateral agreements to attract foreign workers in order to meet their labor supply shortage, developing countries encouraged the emigration of their workers to overcome domestic economic difficulties. These migration flows benefited both the home and the host countries. The most debated issue about the migration flows from the point of view of the home countries is workers’ remittances. Remittances are defined as the money transfers by the migrants residing abroad for more than a year to their home countries. Remittances constituted an important source of external finance for many developing countries. Flows of remittances to developing countries were estimated to be U.S.$167 billion in 2005 (World Bank 2006). Ratha (2003:157) and Adams and Page (2005) draw attention to the fact that workers’ remittances constitute the second largest flow of external finance after foreign direct investment and proved to be the least volatile source of foreign exchange earnings for developing countries.

Several studies found that emigration benefited only the migrants and their families by improving their living standards while it did not contribute to the development of Turkey. Studies based on surveys conducted at different times and various regions of the country supported the view that remittances are mostly used for consumption and personal investments in land and housing. Such views are expressed by Paine (1974: 114), Abadan et al. (1975: 411), Gökdere (1978: 226), Martin (1991: 56), Gitmez (1991: 133) and Koç and Onan (2004: 79). A recent study, Yığit (2005) finds that workers in Germany remit their savings to Turkey with investment purposes rather than consumption purposes. More recently, the weakening of the relation of the second generation Turks with Turkey has led to the use of their savings for investment purposes in Germany.

There have been many studies on the effect of remittances at the household level through surveys in Turkey. To our knowledge, this is the first study on the macroeconomic impact of remittances in a unified framework in Turkey. For this purpose this study estimates a Keynesian dynamic simultaneous equation macroeconometric model for the period 1964–2003 in order to investigate the impact of remittances on key macroeconomic variables such as private consumption, investment, imports and output in Turkey. The dynamic feature of the model enables examination of the over time behavior of the endogenous variables. The estimated impact and dynamic multipliers indicate that an increase in remittances increases consumption, investment, imports and income. The impact of remittances on these variables reduces gradually except that on investment which wears out within one year. The impact multiplier for income implies a substantial increase in income due to remittances through the multiplier process. The remittances-induced output growth rate is compared with the actual...
output growth rate. It is found to be highest in the early 1970s and the early 1980s but appears negligible during the other years. This bodes well with diminishing importance of remittances in recent years. Overall, remittances have been a significant positive factor in the economic development and growth of Turkey. The results are put in perspective by inter-country comparisons. The use of the same model facilitates these comparisons.

The rest of the study is organized as follows. Section 2 presents the over time development of remittances in Turkey. Section 3 presents the dynamic, simultaneous, Keynesian macroeconometric model. Estimation of this model and other empirical results are given in Section 4. Finally, the last section provides the concluding remarks. Data sources are given in the Appendix.

2. Workers’ Remittances in Turkey

Emigration of Turkish workers to Europe started in the early 1960s. Since then Turkey has exported significant numbers of workers mainly to Western European countries. Germany has received the highest number of emigrants among all other European countries. According to official sources (Turkish Labor Office 2001), 1,476 workers went to Germany in 1961 and the highest number (103,793 workers) moved in 1973. Although the number of emigrating workers declined over time due to economic slack in the host countries, as of today there are significant numbers of Turkish migrant workers in Western Europe. In the second half of the 1970s and the 1980s emigration of Turkish workers to the Middle Eastern and North African countries such as Libya, Saudi Arabia and Iraq took place. After 1990, Russia became a major destination country. As of 2001, there were about 2 million Turkish workers abroad and they have generated a significant amount of remittances over time.

The remittances are generally under-reported around the world including Turkey. İçduygu (2006) draws attention to the large informal flows in Turkey and the difficulty in their measurement. This study relies on the official flow of remittances. The sample period stops in 2003 because there is a break in the data after 2003. The Central Bank of the Republic of Turkey reclassified the worker’s remittances together with the tourism revenues since 2004. Therefore, the data before and after 2004 are not comparable.

The remittances were around U.S.$100 million per annum during the 1964–1969 period and increased to over U.S.$1 billion in the early 1970s. They contributed significantly to closing the trade deficits (Boratav 2003: 122). The remittances reached a peak of U.S.$5.4 billion in 1998 (State Planning Organization 2003) and declined during the ensuing period. In 1999 the Russian financial crisis and the two earthquakes that destroyed the industrial heartland of the country adversely affected the Turkish economy. The economic and financial crises in November 2000 and February 2001 brought about substantial declines in output and employment. Mouhoud et al. (2006) argues that these crises could be the main reason behind the decline in the inflow of remittances. The crisis erodes the confidence of the migrants to the economy causing them to remit through unofficial channels or simply not to remit, at least for investment motives.

Figure 1 shows the share of remittances in imports, exports and the GDP over the sample period. These shares reached peaks during the 1973–1976 period. The share of remittances in imports was about 55 percent in 1973, their share in exports was over 90 percent in 1975 and their share in GDP was about 4.5 percent in 1974. There have been substantial declines in these shares after 1999. In 2003 the shares in imports and exports declined to less than 10 percent and the share in GDP declined to less than one percent.

The flow of remittances could be influenced by economic and political crises, and devaluations in the home and host countries as well as by government policies. For instance, Turkish government offered, until recently, differential exchange rates and special interest
rates for foreign currency accounts in order to encourage workers to remit. Similarly, German
government passed regulations to encourage return migration when there was a slack in the
German economy. Such government policies are summarized in Aydaş et al. (2005) which
investigated the determinants of remittances for Turkey. Sayan (2004) and Yiğit (2005)
found that remittances respond to the cycles in the Turkish economy but not to the ones in the
German economy.

3. The Model
The model used is a modification of the model due to Glytsos (2002a, 2002b and 2002c). It is
a linear, demand oriented, simultaneous equation, dynamic macroeconometric model to
determine the effects of workers’ remittances on key macroeconomic variables, such as
private consumption (C), investment (I), imports (M) and income (Y). There are three
behavioral equations, the consumption function, investment function and the import function
and a national income identity. The model allows determination of the short-run and long-run
effects of an exogenous shock of the remittances on the key macroeconomic variables. The
structure of the model is as follows:

\[ C_t = \alpha_0 + \alpha_1 Y_t + \alpha_2 C_{t-1} \]
\[ I_t = \beta_0 + \beta_1 Y_t + \beta_2 K_{t-1} \]
\[ M_t = \delta_0 + \delta_1 Y_t + \delta_2 M_{t-1} \]
\[ Y_t = C_t + G_t + I_t + E_t - M_t + R_t + SD_t \]

\( Y \) is the sum of GDP and the remittances (R). \( K \) is the cumulative gross domestic investment.
\( G \) is the government consumption expenditure. \( SD \) stands for the statistical discrepancy and \( t \)
indicates the time. In this model, \( C, I, M \) and \( Y \) are endogenous variables. The consumption
equation is based on a partial adjustment model. Investment is assumed to be a positive
function of income as a proxy of profits and a negative function of lagged capital stock.
Imports is a function of the level of income and the lagged imports as an indicator of adaptive
expectations. In simultaneous-equations models, ordinary least squares (OLS) estimators are
biased and inconsistent because of the correlation between explanatory endogenous variables
and the stochastic disturbance terms. Two Stage Least Squares (TSLS) method gives
estimates that are consistent and efficient (Intriligator et al. 1996).

4. Empirical Results
There are three types of empirical evidence presented in this section. First, the model
presented in section 3 is estimated for Turkey using annual data for the period 1964–2003
with TSLS. Second, the estimates are used to obtain impact and dynamic multipliers of

---

2 There are several studies which examine the determinants of remittances, such as Glystos (2002c),
who considered the Middle East and North African countries, and Gupta (2005), who considers the evidence from
India. Also, Schiopu and Siegfried (2006) analyze the determination of workers’ remittance flows from 21
Western European to EU neighboring countries.

3 The disturbarance terms are ignored.

4 For instance, if the equilibrium relationship between \( C \) and \( Y \) is defined as \( C_t^* = \beta_1 + \beta_2 Y_t \)
and the dynamic adjustment process is defined by the following partial adjustment model:
\( dC_t = \lambda (C_t^* - C_{t-1}) + u_t \), where \( \lambda \) shows the proportion of the deviation adjusted in any one period. When the first equation is substituted into the second one,
the following equation is obtained \( C_t = \theta_1 + \theta_2 Y_t + \theta_3 C_{t-1} + u_t \) (Stewart and Gill 1998: 186).
Table 1 presents the estimation results of the model. The equations also include dummy variables defined as follows. D1974 takes the value of one in 1974, just after the first oil shock in 1973, and zero otherwise. D2001 takes the value of one in 2001, corresponding to the financial crisis in Turkey, and zero otherwise. DTotal takes the value of one in 1974, 1978, 1980–82, 1994 and 2001 (corresponding to the first oil shock in 1973, the debt crisis, Turkey’s transition period and the economic crises, respectively) and zero otherwise. There is a possibility of a structural break at or near 24 January 1980. At that date, strict foreign exchange controls that were in place since the 1930s were lifted, and the Turkish lira was made convertible. In the pre-1980 period it was common practice for businessmen (who were allocated less foreign exchange by the state than they desired) to buy the remittances of the Turkish workers abroad (at the market rate rather than the lower official rate) and make the payment to their families in Turkey in liras. They would then declare to the state a lower price for their imports than what they actually paid. Thus during this period, remittances and import price indices were under-reported and the value of real imports were over-reported. It would be ideal to enter into the model a variable measuring the difference between the official and the black market rates of the German Mark or the U.S. dollar (interacting with other relevant variables). However the data is not available. After experimenting with various specifications of the dummy variables, only Dtotal, which included the period of 1980, was statistically significant in the import equation, indicating that the periods before and after 1980 were different only for imports.

All of the coefficient estimates, except that of the lagged capital stock, are statistically significant with expected signs. The short-run marginal propensity to consume (MPC) is 0.35. Similar estimates are found by Glytsos (2002b). He found that the MPC estimates are between 0.32 and 0.39 for Egypt, Greece and Portugal and 0.24 for Jordan. Marginal propensity to invest is estimated at 0.33 for Turkey. Glytsos found it to be between 0.13 and 0.39 for all of the above countries except Egypt. The marginal propensity to import (MPI) for Turkey is estimated at 0.16. Glytsos found it to be between 0.14 and 0.40 except for Morocco, with the highest value belonging to Jordan. Using the estimates in table 1, the long-run MPC is estimated to be 0.612 and the long-run MPI is estimated to be 0.518. As expected the long-run values are higher than the corresponding short-run values. Further, the short-run MPC is larger than the short-run MPI while the long-run MPC and the MPI are about the same. These results indicate that consumption is more responsive in the short-run to the changes in income than imports while their long-run responsiveness are about the same.

The reduced form equations express the endogenous variables as a function of all of the predetermined variables in the model. They can be used to find the short-run or impact multipliers. Further, it is useful to determine the dynamic effects of the shocks in the exogenous variables on the endogenous variables. The dynamic or interim multipliers can be derived from the final form equations for the endogenous variables, which are obtained by making continuous substitutions for the dynamic terms (Intriligator et al. 1996). The formulas for the impact and the dynamic multipliers are provided in table 2 and their estimates are given in table 3.

The dynamic multipliers for income are obtained by adding the multipliers for consumption and investment and subtracting that for imports. The dynamic multipliers give the effect of a unit change in remittances in year 1 with no further increase in the subsequent years, with all

---

5 The dynamic (interim) multipliers are calculated for 3 years, since the dynamic multipliers for investment converges to zero in 3 years.
other predetermined variables remaining unchanged. The results indicate that the impact of remittances on consumption, investment, imports and income are all positive in both the short and the long run. The dynamic multipliers are smaller than the impact multipliers. The impact of remittances on investment wears out in the second year while that on consumption reduces only gradually. This may be explained with the Permanent Income Hypothesis which emphasizes the importance of life-time income in spending distributed over time. Glytsos (2002b) finds that the effect of remittances on investment wears out in the first or the second year in Egypt, Greece, Jordan, Morocco and Portugal.

The impact multiplier for investment is close to that of consumption while its dynamic multipliers are essentially zero. The impact and dynamic multipliers for imports are much smaller than that of consumption. The changes in consumption investment and imports brought about by remittances are reflected in changes in income. The impact multiplier for income is substantial. This is similar to the impact multiplier for income obtained for Greece by Glytsos (2002a). The multipliers imply that a 1000 Turkish Liras (TL) increase in remittances leads to a 2079 TL increase in income in year one, 382 TL in year two, 327 TL in year three and 262 TL in year four, through the multiplier effects.

Finally, in this section the impact of a change in remittances on current and future growth rates of output are presented. The estimated impact and dynamic multipliers are used for a four-year time distribution of the effect of remittances on output growth. The following formula is applied:

$$
\Delta Y_t = \frac{\partial Y_t}{\partial R_t} * dR_t + \frac{\partial Y_t}{\partial R_{t-1}} * dR_{t-1} + \frac{\partial Y_t}{\partial R_{t-2}} * dR_{t-2} + \frac{\partial Y_t}{\partial R_{t-3}} * dR_{t-3}
$$

Figure 3 presents the results of this computation for the period 1968–2003 together with the actual growth rates. Remittances appear to contribute to output growth through the multiplier effects in most years. The highest induced growth rate occurs in 1973, which coincides with the first oil shock. For the period 1970–73 the remittances-induced growth rate is 2.7 percent on average. During this period, the remittances contributed to financing the imports of machinery and other intermediate goods increasing domestic output (Russell 1992: 274). After 1973’s first oil shock, most of the Western European countries restricted labor recruitment, which led to a decline in remittance flows. In the early 1980s, the induced growth rates are again relatively high. For instance, for this period the remittances-induced growth rates are 1.6 percent. This is due to the increase in remittances flows with the onset of Turkish migration to the Middle East and North African countries in the early 1980s. For the other periods, the remittances-induced growth rates are either positive or negative and range between 0.5 and 2.0 percent demonstrating moderate effects in either direction, with declining importance of the remittances in the later years. Glytsos (2002b) also found negative induced growth rates in some years for Egypt and Jordan where the overall contribution of the remittances to growth is noteworthy. In Morocco, Greece and Portugal remittances-induced growth rates are observed to take positive as well as negative values but they were very weak in general.

---

6 For details see Intriligator et al. (1996: 31).
7 It is more useful to look at the impact of a change in the remittances in the current period on the future values of the endogenous variable (Stewart and Gill 1998: 184–85).
8 Following the devaluation in 1970, like workers’ remittances, exports increased significantly. Turkish exports were U.S.$588 million in 1970 and increased to U.S.$1.3 billion in 1973. Thus, in the early 1970s, the contribution of exports to growth is noteworthy.
5. Conclusions

To our knowledge, this is the first study on the macroeconomic impact of remittances on the Turkish economy in a unified framework. For this purpose a demand-oriented, dynamic, simultaneous equation, macroeconometric model for the Turkish economy for the period 1964–2003 is estimated using TSLS estimation method. This model was used successfully to measure these impacts in several countries near Turkey or with similar characteristics to Turkey, such as Egypt, Greece, Jordan, Morocco and Portugal. The aim is to analyze the impact of remittances on the key macroeconomic variables. First, the estimates of the consumption, investment and imports equations yielded the marginal propensity to consume (MPC) and marginal propensity to import (MPI) for the short and long run. Second, the impact and dynamic multipliers of a unit change in the remittances on consumption, investment, imports and income were evaluated. Finally, the results were used to evaluate the impact of remittances on current and future growth rates of output with a four-year time distribution of the remittance effect.

The estimated size of the MPC and MPI are reasonable, and comparable to those of the other countries. The estimates for the impact and dynamic multipliers indicate that the impact of remittances on consumption, investment, imports and income are all positive. The impact of remittances on consumption, imports and income reduces gradually while that on investment wears out in the second year. The impact of a change in remittances on consumption, which lasts several years, may be explained with the Permanent Income Hypothesis, which emphasizes the importance of life-time income in spending. The impact and dynamic multipliers for imports are much smaller than that of consumption. The impact multiplier for income is 2.079 which implies a substantial increase in income due to remittances through the multiplier process. It is noteworthy that the remittances-induced output growth rate was mostly positive throughout the period 1968–2003. The highest remittances-induced output growth occurred in the early 1970s—in particular in 1973— which is the year of the first oil shock and corresponds to the period when the share of remittances in GDP and imports was the highest. During this period, the remittances financed the imports of machinery and other intermediate goods increasing domestic production. In the second half of the 1970s, following the labor recruitment ban in Europe, the amount of remittances declined dramatically, and the remittances-induced output growth rates were either very small or negative. In the early 1980s, the Turkish migration to Middle Eastern and North African countries led to an increase in the remittance flows. For this period, the remittances-induced output growth rates were high again. In the 1990s and the early 2000s, although the absolute level of remittances continued to increase, their share in GDP and their relative importance in the Turkish economy declined. During this period, their contribution to output growth was negligible. Overall, evidence provided in this study indicates that the remittances have been a positive factor in the development and growth of Turkey. The findings of this paper have important implications or possible uses in policy making or in making predictions. For instance, while examining the effect of a crisis in Europe on the domestic economy we must consider that not only exports and remittances may be affected, but consumption and investment may also be affected, indirectly, through remittances. Therefore, the results indicate that while making projections, or predictions of consumption and investment, they could be made more accurately by taking the effect of remittances into account. These results may be useful to planners and policy makers.

Appendix: Data Sources

The data of workers’ remittances®, for the period 1964–2003, is obtained from the State Planning Organization (SPO 2003). The data is given in millions of current U.S. dollars. For the same period, average exchange rates are received from the Central Bank of Turkey’s website (Electronic Data Delivery System). The official consumer price index is obtained from the Economic Outlook database (OECD 2008). By using average exchange rates, workers’ remittances are first converted into Turkish Lira (TL). They are then deflated by the consumer price index (base 1987). Thus, real workers’ remittances in terms TL are obtained. The data for private final consumption expenditures (C), government final consumption expenditures (G), gross fixed capital formation (I), exports of goods and services (E), imports of goods and services (I), gross domestic product (GDP) and statistical discrepancy (SD) are all at constant 1987 prices in terms of TL for the period of 1964–2003 and are obtained from the OECD (2008) Economic Outlook database. As a proxy for capital stock, the cumulative gross fixed capital formation is used. The level of Income (Y) is derived as the sum of GDP and workers’ remittances (R).
