Abstract

We study the effect of a corruption reflection index on internal conflict in Iran using a novel measure of corruption based on newspaper coverage. We use the Vector Autoregression (VAR) model and its applied tools of impulse response and variance decomposition analyses to track the response of protests to shocks in the level of corruption. Using annual data from 1962 to 2019, we find a positive and significant response of protests to a positive shock in the news-based corruption reflection index. We also show that the main channels where higher corruption may lead to higher internal protests are through economic growth and military spending.

Keywords: corruption, protest, conflict, newspaper coverage, Iran, economic growth, revolution

1. Introduction

In this study, we examine the dynamic relationships between public corruption and internal conflict using more than 50 years of data in a case study of Iran. We employ the vector autoregressive model, which considers the possible endogeneity of key variables, such as conflict and corruption, and applies impulse response functions and variance decomposition analysis. We aim to understand and measure the response of internal conflict to a positive shock in public corruption, controlling for other important factors. Our measure of conflict is based on three indicators for less violent events of instabilities, such as anti-government demonstrations, general strikes and riots from the Cross National Time Series Data Archive (Banks and Wilson, 2021). Such events have higher frequency and can better reflect the population's anger over mismanagement and corruption. They may also be early warning indicators for more severe forms of conflict, such as the collapse of a political system or civil war.

Over the past 50 years, Iran has experienced a variety of significant political events, such as the popular uprising of 1978-79 and collapse of the monarchy, leading to the establishment of the Islamic Republic of Iran. The revolution was then associated with the eight-years war with Iraq from 1980 to 1988. Following the end of the war, four administrations (Rafsanjani, Khatami, Ahmadinejad and Rouhani) held the office of presidency and control of the government budget from its oil-based economy. In its different forms, grand corruption has been a source of tension during both pre- and post-revolution period. The role of corruption in fueling internal protests is discussed in the traditional press and public spaces, but there has not been a systematic empirical investigation of it in Iran. Lack of historical data on corruption measurement hindered such investigations.

In this study, we introduce a new index of corruption based on reports from one of Iran's main news outlets, *Ettelā'āt* (lit. information), which is the oldest functioning Persian daily newspaper in the world (Parvin, 1988). It has a long history of continuous publication and has tried to be an impartial provider of news. We have followed the methodology developed by Dincer and Johnston (2017) and Dincer and Teoman (2019) in generating the corruption reflection index (CRI) for Iran from 1962 (the earliest year we could access the archives of *Ettelā'āt*¹) to 2019.

¹ We bought Compact Disc of this newspaper archives and investigate them per year.

Besides the issue of corruption data availability, another technical concern was the simultaneous relationship between conflict and corruption. Our methodological approach assumes that all included variables are endogenous and they are interconnected, affecting each other with some optimally selected lag lengths. Using such historical records of data, we simulate the possible reaction of internal conflict to an unexpected increase in public corruption. Our study is therefore related to the literature on the determinants of internal conflict, as well as literature on the consequences of public corruption in oil rich economies. Moreover, it can explain the resource curse, where wealth from natural resources (e.g., oil in our example) can lead to unsustainable development due to corruption and conflict. As a result, we show that the response of internal conflict (based on counted conflict events) to a positive shock in our counted index of public corruption coverage is positive and statistically significant.

Our focus is to track the development of internal conflict following changes in the level of corruption. There are many studies which have quantified the economic effects of internal conflict. For example, Collier (1999) shows that during a period of civil war, countries have 2.2 percentage points less economic growth compared to during peacetime. Different case studies have also looked at the economic loss resulting from internal and external conflicts. For instance, Farzanegan (2020) uses the synthetic control method and estimates a 3000 US\$ average loss of income per Iranian during the revolution and war with Iraq. Similar investigations have been also conducted on conflicts during the Arab Spring and economic growth (Matta et al., 2019 for case of Tunisia; Echevarría and García-Enríquez (2019, 2020) for cases of Egypt and Libya). We are not interested on tracking conflict based only on its significant economic costs. Obviously, conflicts also result in significant human loss. Civil conflicts post World War II have led to more than 16 million casualties worldwide, far more than the human costs of international conflicts (Arbatlı et al. 2020). Farzanegan (2021a) has also quantified the impact of conflict in Iran on the life expectancy of Iranians.

The rest of the paper is organized as follows: Section 2 provides a conceptual framework on the nexus between civil conflicts and corruption. Section 3 describes the data and the empirical strategy. Section 4 presents our results. Finally, Section 5 summarizes and concludes the study.

2. Conceptual framework: The nexus between corruption and civil conflicts

There are different theoretical arguments on the drivers of civil conflicts which can be also used as the framework for the role of public corruption. In this section, we briefly review these theoretical arguments and explain the role of corruption.

a) Opportunity Cost Theory

Incentives to join the civil conflict can be understood through the opportunity cost mechanism. Individuals may decide to join rebellions if the opportunity cost of such behavior is low. That happens under a fragile economic conditions and weak perspectives of long run economic prosperity. Poor institutional conditions, such as high levels of corruption and fragile rule of law and property rights, may shape the opportunity costs of individuals. People under such poor institutional framework may gain more by trying to change the political order. Becker (1968) applied this mechanism and argues that higher wages and employment decrease the level of crime. Grossman (1991) predicts that fewer economic opportunities lead to the higher possibility of rebel. Of course, we can also consider the effect of corruption on the opportunity cost of conflict through its effect on economic growth. The literature is divided on two different effects of corruption on growth. One suggests a positive effect, especially when the regulatory burden is high (greasing the wheels of an economy hypothesis) (Merton, 1957; Huntington, 1968; Leys, 1989). The other argues for the negative effects of corruption, especially in the long term, due its distorting effects on different sectors of economic and political structures, presenting the sanding the wheels of an economy hypothesis (Gründler and Potrafke, 2019). In the latter case, there may be a significant reduction in the opportunity costs of participating in civil protests. Investment in countries with higher levels of corruption is associated with higher risk. Thus, we expect lower levels of investment in corrupt countries where corruption has an unpredictable nature (Campos et al, 1999). As a result of lower investment, unemployment may increase. Corruption increases the cost of production which transfers to consumers through higher consumer prices and inflation. A combination of higher unemployment and inflation leads to lower opportunity costs for people in such an economic system to join rebellions. This was also the case in the rapid expansion of the Boko Haram terrorist organization in Nigeria (Onuoha, 2014), and Taliban in Afghanistan (SIGAR, 2016).

b) Collective Action Theory

While the opportunity cost mechanism may explain the decision of an individual to join protests, participation in such civil protests has a problem of collective action as well. Protests are collective, and in such actions, there is a problem of “free-riding” (Samuelson, 1964). When a selected part of population bears the cost of public activities (such as protests), other people may benefit from the result of such activities without paying the associated costs. Free riding can hinder the successful mobilization of different segments of the population against political power. In such situations, some significant economic, political or natural events may decrease the cost of participation in collective action (Bazzi and Blattman, 2014). Price shocks or large-scale corruption scandals may act as catalyzers to solve the collective action problem, especially when other alternatives for the deprived population are not available (Ishak and Farzanegan, 2021). An example is the shock of a sudden significant increase in gasoline prices in Iran in 2019 by the government during a significant decrease in oil income under sanctions. In response, countrywide anti-government demonstrations formed (Fassihi and Gladstone, 2019).

c) Grievance and Deprivation Theory

“Grievance” and “deprivation” are two other argued factors behind the formation of protests and civil conflicts. The central idea in this debate is the gap between the expected and actual condition of an individual. If this gap increases, the perception of deprivation increases as well. For example, while economic conditions deteriorate because of growing corruption, people compare their welfare and real purchasing power with years before such negative shocks and the perception of deprivation increases. Campante and Chor (2014) explain that as the gap between real and expected income of people with higher levels of education arises, the probability of participating in protests increases. Higher rates of corruption increase the sense of deprivation (Arampatzi et al, 2018). Higher relative deprivation increases the probability of participation in protest activities (Kurer et al, 2019). Moreover, Grasso and Giugni (2016) show that the final effect of an individual’s subjective feelings of deprivation on protest behavior depends on macroeconomic and policy factors.

d) Mobilization and Media Effect Theory

This branch of theoretical debate covers political process (Tilly, 1997), resource mobilization (Jenkins, 1983; Zald, and McCarthy, 2002), and social media effects (Jost et al, 2018; Valenzuela et al, 2016). In this category, corruption can also affect protests through social mobilization (Beyerle, 2014; Lewis, 2020). Social media has a positive effect on the number and participation rates of protests. Qin et al (2019) use a dataset of 13 billion microblog posts in China during 2009-2013 and find that social media networks increase the spread of protests and strikes. They also find that corruption is an important driver of protests (e.g., protest farmers in Guangdong province against the corruption of local officials in 2011). Enikolopov, Makarian and Petrova (2020) show that the penetration of VK, the largest social network in Russia and the CIS, was one of the main drivers of protests in Russia in 2011. They also argue that the expansion of social media reduces the coordination costs for protests, resulting in faster expansion of protests in Russia. In addition, political opponents may use mass media to mobilize people in anti-corruption protests, as these protests can strengthen them (Annan, 2014; Školník, 2021).

e) Modernization Theory

Under modernization theory, the probability of protests may increase during the economic modernization process. Huntington defines modernization as a multidimensional process ‘involving changes in all areas of human thought and activity’ (Huntington, 1968, 52). Under specific conditions, modernization may result in instability and conflict. An increasing number of an educated population during modernization process may also increase expectations for better job opportunities. The inability of economic growth in generating productive jobs may lead to higher unemployment rates especially among educated youth. This outcome may reduce the opportunity costs of engaging in civil conflict. Campante and Chor (2012) explain that a significant increase in years of schooling in the Middle East and North Africa region during 1980-2010 played an important role in protest and revolutions (such as the events during Arab Spring). Economic modernization may increase internal migration from rural areas to urban ones and result in fast urbanization rates and a bigger slum population. If the new migrants who have lost their traditional jobs in rural areas do not integrate in the urban economy, there may be higher rates of urban unemployment, crime and instability. Economic modernization may also increase the income gap between the rich (who may have larger capital and soft skills) and the poor (who often

lack such physical and human capital).² Growth in income inequality can foster instability and the risk of conflict or domestic terrorism (Krieger and Meierrieks, 2019).

f) Imbalance Development Theory

Hibbs (1973) examined the effect of economic and social development on mass violence. He finds that imbalances in education and urbanization may lead to uneven in economic development. In addition, social mobilization, government performance and social welfare can affect social structural imbalances. Uneven economic development and social structural imbalances lead to the systemic frustration of the population. Abrahamian (1982) explains the reasons of protests in Iran during 1977-1979 with the idea of imbalance development. Corruption contributes in imbalanced development as it distort the allocation of government budget to the military and security sectors, leaving public education and health underfunded. Corruption also has significant deteriorating effects on the quality of environment and amplifies the impact of the shadow economy on the environment (Biswas et al, 2012). The latter is a critical factor for balanced economic growth in the long term. Farzanegan (2021b) and Farzanegan and Hofmann (2021) also show that corruption deteriorates the capacity of the health sector to manage crises and results in higher human costs during pandemics.

g) Political Participation Theory

Bonifácio and Paulino (2015) explain political participation as “activities exercised by citizens, in several areas with the objective of influencing the dynamics of power”. Government performance and the legitimacy of government are major elements which affect people’s decision to choose the type of political participation (Della Porta, 2000). When people trust democratic institutions, they choose voting and non-violent activities, while they may participate in violent activities when they lose their faith in the current political system (Warren, 2004). Corruption in the form of clientelism and cronyism has a negative effect on trust in the political system (Etzioni-Halevy, 1985), which can increase the probability of protests. Corruption also has a negative effect on democracy (Rose-Ackerman, 1999) and can erode political democratic institutions (Warren, 2004).

² Farzanegan and Krieger (2019) show the positive (increasing) response of income inequality to oil booms and expansion in the financial market and foreign trade in Iran.

3. Research design: hypothesis, data, and empirical method

Based on the discussed theoretical channels through which corruption may affect internal conflict, we formulate and test the following hypothesis in the case of Iran, using annual data from 1962 to 2019:

Hypothesis: The response of Iran's protest index to positive shocks in the corruption reflection index is positive, *ceteris paribus*.

3.1. Description of variables and data

We aim to measure the dynamic connection between internal conflict and level of corruption reflection within Iranian society. Our main measure of internal conflict is based on Domestic Conflict Event Data from the Cross-National Time-Series (CNTS) Data Archive (Banks and Wilson, 2021). CNTS conflict data are based on the theoretical framework presented by Rummel (1963). It uses the coverage of different events in major international newspapers (e.g. The New York Times) and other additional reliable online news reports, reporting events such as assassinations, general strikes, terrorism/guerrilla warfare, major government crises, purges, riots, revolutions and anti-government demonstrations. This data has been used extensively in conflict studies.³ We follow Ishak and Farzanegan (2021) and use the sum of events under riots, strikes and anti-government demonstrations, which have a higher chance of occurring as a response to the institutional performance of a country, generating our news-based protest index. Figure 1 shows the development of protest index in Iran from 1962 to 2019.

³ A list of such studies using CNTS data is presented at <https://www.cntsdata.com/citations>

Fig. 1. Protests in Iran. Source: Number of protests is from Banks and Wilson, 2021.

One of the main drivers of protests and conflict in the literature is the perception of corruption and its degree of reflection in society. We focus on tracking the reflection of corruption, in its broad term and variations, in one of the major newspapers of Iran, *Ettelā'āt*. This newspaper is well-known to be a moderate outlet in reflecting the political, economic and social events in Iran with a broad readership. We follow Dincer and Johston (2017)) and Dincer and Teoman (2019) for generating the corruption reflection index for Iran.

We chose *Ettelā'āt* because it is one of the oldest daily newspapers in Iran (founded in 1926) and covers economic, social and political issues. The archive of *Ettelā'āt* is accessible from 1961. *Ettelā'āt* archives are digitized from 1961 and all pages for each month are copied to a compact disc (CD). To extract all the data, we searched within 12 CDs for each year from 1962 to 2019. We searched for the Persian keywords related to corruption “فساد”, “رشوه”, “اختلاس”, and “کلاهبرداری” (Persian counterparts for the words “corruption”, “bribe”, “embezzlement”, and “fraud”). We included “embezzlement” keyword in our research, although Dincer and Johston (2017) and Dincer and Teoman (2019) did not. From 1962 to 1990, both keywords “bribe” and “fraud” were the most common in the *Ettelā'āt* newspaper, but since then, we observed “corruption” and “embezzlement” more in media coverage.

We define some criteria to determine which article or text is relevant to our index. First, as CRI covers corruption in public sector, we do not count the page or article which are related to charges against the private sector, unless that private person has close ties with public officials. We included corruption cases related to non-profit organizations in Iran due to their direct and indirect association with government. We do not consider references to corruption in political slogans and statements of political rival groups for which there is no verified evidence.

Following Dincer and Teoman (2019), we consider the corruption of public officials when they are in power. However, we count such cases even if that person is no longer in government. In most cases, former members of the government or parliament in Iran have been appointed to senior positions in non-profit organizations, foundations or government-owned companies.

In line with Dincer and Teoman (2019), we focus on the time of the reported corruption in the newspaper instead of the timing of act of corruption. Moreover, we exclude references to corruption which are not related to economic or financial issues (i.e., references to moral corruption in society). In other words, we consider the context in which the related terms are mentioned.

Figure 2 represents the CRI from 1962 to 2019 for Iran and Table 1 explains its statistical description. As Figure 2 shows, the trend of corruption is decreasing during the 1960s and the CRI is low. At the beginning of 1970s, the level of CRI is low, but there is a considerable increase thereafter. One reason for this is the significant increase in oil revenues in 1973. After the oil boom many new contracts were formed in the public sector to absorb this revenue. However, the structural constraint of the economy and low levels of audit led to more corruption. We show all main political or economic events with possible effects on CRI in Figure 2. Moreover, as the summary statistics of the CRI in Table 1 shows, the level of CRI is completely different in five years before the Islamic revolution of 1979. To have a historical perspective, we explain all main reports about corruption in the *Ettelā'āt* newspaper in various years in the Appendix (Table A). Most reports from 1962-1966 refer to the corruption of the military sector. After that, the *Ettelā'āt* newspaper covers corruption in Western countries, especially in 1972 and 1973. After the oil boom in 1973, the level of corruption changed significantly. In 1974, new networks of corruption were detected, and various corrupt people escaped to the United States in 1976 and 1977. For the first time since 1962 (the beginning of our research), fighting corruption became the

main political agenda. In 1977, anti-corruption law was approved and various related committees were established. In this period, there was frequent coverage of corruption cases in different public sectors such as postal services, telecommunication, municipalities, and state-owned enterprises.

Fig.2. Corruption reflection index in Iran (1962-2019).

Table 1. Summary statistics of CRI

| | Average | Max. | Min. | Std. Dev. |
|-----------------------------------|---------|------|------|-----------|
| Total Duration (1962-2019) | 40.3 | 127 | 5 | 29.5 |
| Before revolution (1962-1979) | 27.1 | 68 | 5 | 22.5 |
| After revolution (1980-2019) | 45.7 | 127 | 7 | 30.3 |
| Last five years before revolution | 57.6 | 68 | 43 | 8.6 |
| Last two years before revolution | 63.0 | 68 | 58 | 5.0 |
| First two years after revolution | 17.5 | 24 | 11 | 6.5 |
| First decade since revolution | 24.4 | 41 | 8 | 9.8 |
| Hashemi Rafsanjani government | 48.6 | 96 | 25 | 23.9 |
| Khatami government | 22.1 | 38 | 7 | 9.0 |
| Ahmadinejad government | 61.1 | 127 | 28 | 34.5 |
| Rouhani government | 82.4 | 105 | 62 | 14.2 |

After the 1979 revolution, the level of CRI decreased. In the first two years after revolution, revolutionists tried to investigate the corruption cases related to the previous political regime. From 1980 to 1985, corruption reports in the *Ettelā'āt* newspaper covered corruption in both Western and Eastern countries. Moreover, revolutionists had some ideas to fight corruption in the Muslim world in 1982 and offered suggestions to UNESCO to fight against corruption in 1986. From 1984, for the first time since the revolution, corruption within economic companies or politicians' relatives are covered in the *Ettelā'āt* newspaper. This newspaper covered a \$2 million corruption scandal in a ministry in 1985. Moreover, due to the Iran-Iraq war, the multiple exchange rate system and price discrimination was applied to the Iranian economy and raised the level of CRI, in comparison to the initial years of revolution (see Farzanegan, 2009 and Farzanegan, 2013 for discussions on black market premium in Iran). After the war with Iraq, economic adjustment policy was the main agenda of the Hashemi Rafsanjani government for reconstruction of the Iranian economy, reducing the size of government and promoting privatization and liberalization. Economic liberalization was not associated with political openness and we observe a surge in the level of corruption. Moreover, municipalities appeared in corruption cases from 1991 and various related cases detected in 1993 and 1994. For the first time since revolution, a major corruption scandal of 1230 billion *rial* (\$702.85 million), by two persons (Khodadad

and Rafighdost) was detected in 1994. Due to the execution of Khodadad in 1995 and corruption in banking system, CRI in 1995 reached more than 60, a record since the Islamic revolution.

During the Mohammad Khatami reformist government (1997-2005), CRI decreased notably, reaching its minimum level since the revolution. Although CRI was low in the first three years of the Khatami administration, it increased in his second term (2001-2005). In 2001, some corruption scandals (approximately \$4.5 million) were detected, and the anti-corruption decree of Ayatollah Khamenei (Leader of Islamic Republic) was declared. Moreover, Shahram Jazayeri, an Iranian businessman, who was involved in a high-profile corruption case through connections with influential public officials, was arrested in this year. Although the level of corruption increased in the Khatami's second term, but unification of the exchange rate regime in 2002 and reform of the tenders' law in 2003 were two fundamental reforms which increased the level of transparency in public investment projects. Moreover, the Khatami government promoted freedom of the media and the engagement of civil society in political debates that led to higher level of transparency too.

In August 2005, Mahmoud Ahmadinejad was elected as Iran's president. His office was also associated with a series of international economic sanctions on Iran due to its nuclear program, distorting markets such as the currencies, which increased black market premiums and new rent-seeking opportunities. Banking and oil embargos also increased transaction costs, resulting to application of different methods and channels to bypass them by Iranian authorities (see Farzanegan, 2013). In 2007, Shahram Jazayeri escaped from prison in February but was rearrested by the Ministry of Intelligence of Iran in March.

In 2011, Mahmoud Reza Khavari, who was appointed as chairman of *Bank Melli Iran* (National Bank of Iran) by Ahmadinejad in 2010 and head of *Sepah Bank* during Khatami's presidency, was accused of embezzling approximately \$2.6 billion. He escaped to Canada. In 2020, Iran's Interpol Chief Brigadier-General Hadi Shirzad announced that Iran has protested to the Interpol chief over Canada's lack of cooperation in returning Khavari to Iran over his corruption scandal⁴.

In another major corruption case in Iran's banking history, a businessman, Mahafarid Amir-Khosravi, and 39 other individuals were convicted in 2011 over their involvement in money laundering, forgery

⁴ <https://en.irna.ir/news/84112325/Iran-protests-to-Interpol-for-Canada-s-lack-of-cooperation>

and bribery at private and state banks from 2007 to 2010. The arrest and escape of Khavari was connected to this case. Amir Khosravi and his team used fake documents to obtain large credits, which were partly used to buy government-owned companies under the privatization plan of government⁵. He admitted to bribing Khavari and others in the Iranian banking system to facilitate access to banking credits. He was executed by hanging in Evin Prison in Tehran on May 24, 2014. This case was comparable (but not in size) with the 1995 execution of Fazel Khodadad over a \$400 million corruption case at *Bank Saderaat*. None of the Ahmadinejad top officials convicted over this case.⁶

Due to various corruption cases and high levels of embezzlement, the CRI in 2011 has its highest level in our study. The economic and oil sanctions against Iran started in 2011/2012 and the relative value of Iran's currency (*rial*) per dollar decreased significantly. It resulted in higher levels of inflation and unemployment. Zamani et al. (2021) show the positive effect of sanctions on the black market premiums of Iran's currency. In 2013, the eight years of Ahmadinejad's government ended and Hassan Rouhani took office. During the Rouhani administration we also observe a high level of CRI. His administration was associated with the partial lifting of sanctions in 2016 and 2017 and consequent reinstatement under the Trump administration's "maximum pressure" campaign against Iran. The main corruption and embezzlement scandals covered in newspapers during his first years of government (2013-2016) includes the "*Taavoni Farhangian*" reserve fund⁷ (corruption of approximately \$ 2.7 billion), the case of another politically connected businessman, Babak Zanjani⁸ (estimated \$3.5 billion), and the case of a missing oil rig (estimated \$87 million)⁹. The corruption cases continued in Rouhani's second term. Following the reinstatement of economic sanctions on Iran by the Trump administration, the price of dollar (relative to Iranian currency (*rial*)) and gold coin fluctuated significantly. Vahdid Mazlumin

⁶ <https://www.al-monitor.com/originals/2014/05/iran-businessman-hanged-embezzlement.html>

⁷ This is a reserve fund for about one million teachers.

⁸ Long before the imposition of sanctions, he was employed as a driver for Iraq's Central Bank. He was supposed to help the Iranian government bypass oil sanctions, using his large banking networks. He was arrested under the Rouhani government. Bijan Zanganeh, the former Oil Minister under Rouhani called him a "corrupt parasite". Zanganeh said that "Zanjani's total debt, including its interests, amounts to \$3.5 billion." Babak Zanjani was sentenced to death in 2016 on charges of embezzling money earned from black market oil exports. See <https://www.bbc.com/news/world-middle-east-35739377> and <https://en.radiofarda.com/a/iran-billionaire-zanjani-to-be-hanged-after-he-pays/29656321.html>

⁹ <https://www.reuters.com/article/us-iran-oil-scandal-idUSKCN0R41I920150904>

(known in Iran as the Sultan of Coins) was accused of hoarding two tonnes of gold coins to manipulate prices. He received the death penalty for “spreading corruption on earth” and was executed in 2018¹⁰.

In another example, in 2019, media executive Marjan Sheikholoslami and a group of business executives were accused of profiting from the country’s multiple exchange rate regime while assisting the Iranian Petrochemical Commercial Company to evade sanctions under President Ahmadinejad. The accused either failed to reimburse government companies in hard currency - converting the proceeds to local currency at the low official exchange before returning the money, thus making a profit - or outright embezzled.¹¹ They are accused of withholding foreign exchange that was sold for up to three times the formal rate on the black market. Most of the suspects in this case were reportedly managers of the Iranian Petrochemical Commercial Company at the time of detection (Faghihi, 2019). Sheikholeslami had a background in Iranian journalism and politics as well. She was a political writer for the Reformist daily *Hambastegi*. She also managed the Cultural Heritage News Agency in the early 2000s. Moreover, she participated as a reformist candidate in the 2000 parliamentary elections and later on as a conservative in the 2008 legislative polls (Faghihi, 2019).

Due to various large scale corruption scandals in the Rouhani administration, the CRI average reached its the maximum level. Table 2 summarizes selected major (nonpolitical) corruption scandals in Iran.

Table 2. Major (nonpolitical) Corruption Scandals in Iran

| | Prisoned | Executed | Escaped (to...) |
|-----------|------------------|--------------------|--------------------------------------|
| 1976-1977 | | | Corrupt people (to the U.S.) |
| 1995 | | Fazel Khodadad | |
| 2001 | Shahram Jazayeri | | |
| 2011 | | | Khavari (to Canada) |
| 2013 | Babak Zanjani | | |
| 2014 | | Mahafarid Khosravi | |
| 2018 | | Vahid Mazlumin | |
| 2019 | | | Marjan Sheykholeslami (to Canada) |

To check the reliability of the CRI, we compare it with the perception based control of corruption index (CCI). The CCI is constructed by the World Bank and ranges from -2.5 to 2.5, a lower index represents a higher perception level of corruption. The correlation between the CRI and CCI is -0.79. The words “bribe”, “embezzlement” and “fraud” in the CRI are covered in the CCI too. These results show that the news based CRI for Iran is reliable. Moreover it covers more than a half-century of data.

In theory, we may expect that more media coverage of economic corruption cases may increase the perception of it across the country and may trigger the frustration and disappointment of the people. It increases the perception of inequality and relative deprivation, lowering confidence in the government and may decrease the opportunity costs of engaging in protests. However, a higher level of public corruption, especially in oil rich countries, may facilitate the accommodation of private interests through a more comfortable distribution of resource rents in different forms, such as heavy subsidies and large public employment. This is discussed by Fjelde (2009) in the context of civil war, suggesting that “political corruption can be used to accommodate opposition and placate restive groups by offering private privilege in exchange for political loyalty.” It is shown that governments may use public sector employment as a redistributive tool, mainly for patronage goals to secure re-election (Bjorvatn and Farzanegan, 2013). It is therefore interesting to explore how protest activities in Iran have responded to increases in the corruption reflection in society, using the history of 58 years of data.

While our focus is on the relationships between conflict and corruption, we also control for other confounding variables which may be correlated with both variables. One channel through which corruption may affect internal conflict is through its impact on the level of economic development. The effect of corruption on income per capita is extensively studied in the literature. Some studies find

empirical evidence for the greasing the wheels hypothesis, which implies the positive effects of corruption on economic growth with the presence of significant regulatory burden. Others have shown negative impacts of corruption on development and support the sanding the wheel hypothesis, since corruption distorts the allocation of government budget and the allocation of talent from productive to unproductive activities. Corruption leads to higher educational and income inequality, which is a main driver of conflict. It also results in higher transaction costs, economic uncertainty, and reducing investment (especially when corruption has an unpredictable nature). Higher corruption increases costs of production and imports costs which lead to higher consumer prices and inflation. The latter is also a driver of protests. Corruption is driver of instability especially with the presence of a significant youth bulge in a population. By lowering the level of economic development and increasing the inflation rate, corruption may reduce the opportunity costs of involving in violence. We also control for the inflation rate which, as explained earlier is one of the channels through which corruption is related to conflict. Oil revenues in a country such as Iran is an important factor for stabilizing or destabilizing country. Oil rents are both related to corruption and conflict. It is shown that countries with a higher reliance on rents are more prone to corruption. Oil rich countries, on average, have a lower quality of democratic institutions, which may reduce transparency and increase the risk of engaging in corruption. Oil and its negative effect on the fiscal relationship between the state and the people reduces the degree of government accountability (as oil replaces taxes). Oil rents may also stabilize the political system if the state uses financial leverage of oil rents to satisfy the economic needs of the people through direct and indirect transfers of rents, reducing the risk of regime change.

3.2. Methodology

To study the response of internal conflict to a positive shock in the news-based corruption index, we use a vector autoregressive (VAR) model (Sims 1986).

A structural form VAR is written as follows:

$$A_0 Y_t = \alpha_0 + A_1 Y_{t-1} + A_2 Y_{t-2} + \dots + A_p Y_{t-p} + u_t \quad (1)$$

where Y_t is a $(m \times 1)$ vector of endogenous variables at time t ; α_0 is a $(m \times 1)$ vector of constants; A_i ($i = 1, 2, \dots, p$) is a $(m \times m)$ vector of structural parameters and u_t is a $(m \times 1)$ vector of structural shocks. We cannot directly estimate the parameters of a structural VAR in Equation (1). To do so, we multiply equation 1 by the inverse of matrix A_0 , resulting in a reduced form VAR model (Eq. 2). We estimate the reduced form by using the Ordinary Least Squares (OLS) method.

$$Y_t = g_0 + G_1 Y_{t-1} + G_2 Y_{t-2} + \dots + G_p Y_{t-p} + e_t \quad (2)$$

where Y_t , which is a vector of endogenous variables, depends on its own lags and the lags of other endogenous variables. The forecast error vector e_t ; $e_t = A_0^{-1} * u_t$ is a linear combination of structural shocks (u_t). We need to recover the structural parameters in equation 1 from the estimated parameters in equation 2, which is called the identification process in VAR (Sims 1986).

Using economic and institutional intuition and theoretical discussions, we need to impose restrictions on matrix A_0 (which is the matrix of the contemporaneous links among the endogenous variables of the structural model) for identification of the VAR model. The reason for imposing such restrictions is that the number of unknown elements of a structural VAR are larger than the number of known elements from an estimated reduced VAR model (Nguyen et al., 2019). The number of restrictions depends on the number of endogenous variables in VAR. If there are m endogenous variables in the VAR model, we need to impose $m \times (m-1) / 2$ restrictions (Gujarati 2009). The Cholesky decomposition is one of the popular methods of imposing restrictions on matrix A_0 which assumes that this matrix is a lower triangular matrix. According to this approach, the variables at higher levels of ordering influence the other variables at lower levels of ordering contemporaneously but are affected by them with some time lags. The variables with more exogenous nature are ordered higher in this approach and the more endogenous ones following. An alternative approach in the identification of a VAR model is structural decomposition in which matrix A_0 can have another structure with different restrictions. Following Nguyen et al. (2019) and others, we prefer to use recursive identification (Cholesky decomposition) instead of structural decomposition as the former imposes fewer restrictions.

As the ordering of variables may influence the post-VAR estimations for the impulse response analysis (IRF), we also use the generalized VARs (GVARs) introduced by Pesaran and Shin (1998) and report the generalized IRFs which are invariant to the variable ordering of a VAR model. Our preferred ordering of variables is as following: [corruption, inflation, GDP growth, protest, oil share of GDP, non-military spending share of GDP, military spending share of GDP]. The Granger causality results also support this ordering. An increase in corruption cases affects the inflation rate contemporaneously. Corruption is shown to increase the costs of production and transactions which will be easily transferred to consumers. Increasing inflation shows higher price volatility and higher costs of monitoring economic agents. It also reduces the purchasing power of public agents and increases the probability of demanding extra-legal payments in public sector. Inflation can enhance corruption with a lag. The empirical support for the corruption-inflation nexus is presented by Braun and Di Tella (2004). Higher inflation also shows a short-term negative impact on real GDP growth rates while the latter affect the supply and demand nexus with a lag. For strong evidence on the negative impact of inflation on economic growth and efficiency and which productive factors are used, see Andrés and Hernando (1997). Decreasing real GDP growth rates following higher corruption and inflation reduces the economic opportunity costs of engaging in protests, increasing the risk of internal conflict. For evidence on the effect of economic growth on internal conflict, see Brückner and Gradstein (2015). Oil export revenues as a share of GDP influences economic growth and can affect it with a lag. Government spending (military and non-military) as a share of GDP is influenced by the development of oil export revenues and other variables ordered at the top of the ranking in the short term. Government budget allocation influences economic growth and the opportunity costs of engaging in conflict with a lag.

To estimate the VAR model, including the above-mentioned seven variables, we need to decide on the optimal lag length, checking the stationarity of the estimated VAR model and making sure that the estimate VAR model does not suffer from residual autocorrelation at selected lag lengths. Table 3 shows the results of optimum lag selection. Based on SC and HQ criteria we select the lag length of 1 to estimate the VAR model.

Table 3. VAR Lag Order Selection Criteria

Sample: 1962 2019, Included observations: 54

| Lag | LogL | LR | FPE | AIC | SC | HQ |
|-----|-----------|-----------|-----------|-----------|-----------|-----------|
| 0 | -1230.726 | NA | 1.91e+11 | 45.84169 | 46.09952 | 45.94112 |
| 1 | -1084.947 | 248.3626 | 5.39e+09 | 42.25731 | 44.31996* | 43.05280* |
| 2 | -1036.053 | 70.62579 | 5.92e+09 | 42.26121 | 46.12868 | 43.75274 |
| 3 | -975.4305 | 71.84851* | 4.92e+09* | 41.83076* | 47.50305 | 44.01834 |
| 4 | -929.6271 | 42.41060 | 9.41e+09 | 41.94915 | 49.42626 | 44.83278 |

* indicates lag order selected by the criterion

LR: sequential modified LR test statistic (each test at 5% level), FPE: Final prediction error, AIC: Akaike information criterion, SC: Schwarz information criterion, HQ: Hannan-Quinn information criterion

The estimated VAR model should be also stable (stationary). If it is unstable, some critical results such as estimated confidence intervals for impulse responses, are not valid. We have examined the stationarity of each of the included seven variables. Three variables (oil export revenues as share of GDP, military spending and non-military spending as share of GDP) are integrated of the first order while the other four variables are stationary in levels (Augmented Dickey-Fuller (ADF) and Phillips-Perron (PP) unit root tests are available upon request). According to Lütkepohl (2005), the overall stationarity condition of a VAR model is more important than the stationarity of each single series. Following previous studies, we are estimating our VAR model in levels of variables as the results of the stability condition show the whole estimated model is stationary and stable (see Figure 3). Previous studies have also used the level of the variable , especially when the focus is on the interpretation of impulse responses (e.g., Sims, Stock, and Watson,1990; Sims, 1992; Elbourne and de Haan 2009; Farzanegan and Markwardt, 2009; Dizaji et al., 2016; Nguyen et al, 2019, among many others). According to Hamilton (1994), even if the true model is a VAR in differences, the specific functions of the parameters and hypothesis tests based on a VAR in levels have the same asymptotic distribution as when estimated based on VAR in differences

Figure 3. VAR stability condition
Inverse Roots of AR Characteristic Polynomial

No root lies outside the unit circle. VAR satisfies the stability condition.

Moreover, the estimated VAR model shows no residual correlation at the selected lag length of one.

Table 4 shows the Lagrange Multiplier (LM) test for autocorrelation. The p-value of 0.23 indicates that we cannot reject the null hypothesis of no residual autocorrelation at the lag of one.

Table 4. VAR Residual Serial Correlation LM Tests

| Lag | LRE* stat | df | Prob. | Rao F-stat | df | Prob. |
|-----|-----------|----|--------|------------|-------------|--------|
| 1 | 55.98264 | 49 | 0.2293 | 1.16271 | (49, 187.2) | 0.2368 |
| 2 | 71.05365 | 49 | 0.0214 | 1.532204 | (49, 187.2) | 0.023 |

4. Results

4.1. Impulse response functions

In this section, we examine the response of variables in our estimated VAR model to a positive shock in the corruption reflection index. We employ the impulse response functions (IRF) which trace responses to such shocks over time, indicating the direction, magnitude and significance of the responses. Our focus is on the response of protests to a positive shock on the corruption index, while aiming to shed some light on possible transmission channels. Following Sims and Zha (1999) and Stock

and Watson (2001), we report one standard deviation for error bands in the IRFs (68% confidence intervals).¹² To compute impulse response standard errors, we follow Killian's unbiased confidence interval (Killian, 1998). This bias-corrected bootstrap interval approach explicitly corrects for the bias and skewness in the impulse response estimator that arises due to insufficient observations and thus is more relevant for our case study of Iran with annual data.

Figure 4 shows the response of protests and other included variables to a shock (measured by a one standard deviation increase) in the news-based corruption reflection index. According to IRF in Figure 4, the response of protests to the positive shock in the corruption reflection index is positive and statistically significant for the six years after the initial shock. The maximum increase in protests is about two protests in the first year after the shock, reducing to one protest by the third year. The size of the short-term response of our counted index of protests (including number of riots, strikes and anti-government demonstrations) is significant given the mean of 3.7 and median number of 1 over the 1962-2019 period. This finding supports our main hypothesis of the increasing effect of corruption scandals on internal conflict in Iran.

To what extent are the results in Figure 4 sensitive to the ordering of variables in the estimated VAR model? To check this issue and continue our discussion, we report the Generalized IRF which is insensitive to variable ordering. Figure 5 shows the responses to a generalized one standard deviation positive shock in the corruption reflection index. There are some minor differences but overall, the direction and magnitude of responses are similar to the previous results. We consider the significant response of protests to positive shocks in corruption. The highest response is observed within the first 2 years after the shock and remains statistically significant for the following 6 years.

The results contain some more useful information on possible channels through which protests may expand following an increase in corruption. For example, we observe that the response of inflation rate to the corruption shock is positive and statistically significant within the first six years following the shock. The maximum response of inflation is observed in the second and third years after the shock (increase of 2 percentage points). An increase in corruption cases is associated with higher costs of doing

¹² The main result of response of protest to corruption shock is also significant at 95% confidence intervals.

business and transactions which may lead to higher production costs. The producers transfer the cost to consumers and thus consumer prices will also increase. It is also shown that an increase of inflation by reducing household disposable income reduces the opportunity costs of participating in protests. Although this effect is theoretically plausible, the response of protests to a positive shock in the inflation rate in Iran is not statistically significant. This may be related to the higher costs of participating in protests (e.g., high repressive power of the state and severe consequences for the arrested participants) which exceed the costs imposed on them by higher inflation.

There are two other interesting observations. The response of non-military spending to a positive shock in the corruption reflection index of Iran is negative and statistically significant from the second period following initial shock. The non-military spending of Iran (which is calculated as the difference between the total government spending share of GDP and its military spending share of GDP) reaches its minimum level by 5th year after the shock. As also shown in the literature, there is a positive association between corruption and military spending. The response of military spending of Iran is positive and statistically significant for the first 2 years after the shock. Military projects have lower levels of transparency and lower risk of detection of corruption. They are also prone to more corruption due to higher transaction values. According to the Transparency International Government Defence Anti-Corruption Index, Iran is in the high-risk category for corruption in the defense and security sector. The country's highest risk area is finance and procurement.¹³ Our further investigation supports our prior expectation that the response of protests to a positive shock in military spending is positive and statistically significant in the second year after the shock. The response of protests to a positive shock in the military spending of Iran reaches its maximum in the second year after the shock (an increase by one protest). An interesting point is also the negative response of economic growth rates in Iran to a positive shock in military spending. Of course, the negative response of economic growth to an increase in military spending is only marginally significant in the first year after the shock. Increasing military spending is also associated with a decreasing non-military spending relative share. This is also evident in the negative response of non-military spending to a positive shock in military spending. This negative

¹³ <https://government.defenceindex.org/downloads/docs/iranislamicrep.pdf>

response is statistically significant within the first 2 years after the shock (results are available upon request).

One important channel through which corruption may influence the number of protests is overall economic growth. The response of GDP growth rates to a positive shock in the corruption index is negative for the entire 10 years after the shock. This negative response is statistically significant for the initial six years after the shock. The minimum response of economic growth is reached by the third year after the shock (approximately 1.5 percentage points decline). Our further investigation shows the significant negative response of the number of protests to a positive shock in economic growth rates. This decreasing response of protests is statistically significant for the first 2 years following the shock. Protests response to a positive shock in economic growth is at its lowest levels in the first 2 years (a drop of 1.5 events). Positive shocks in economic growth rates in Iran are associated with the negative responses in inflation, which is statistically significant for the first 5 years after the shock, decreases in military spending, which is statistically significant for the first 2 years and increases in oil exports revenues, which is significant for whole period after the shock. The last finding highlights the strong association between oil rents and economic growth in Iran, which is also shown by other studies (e.g., Farzanegan and Markwardt, 2009).

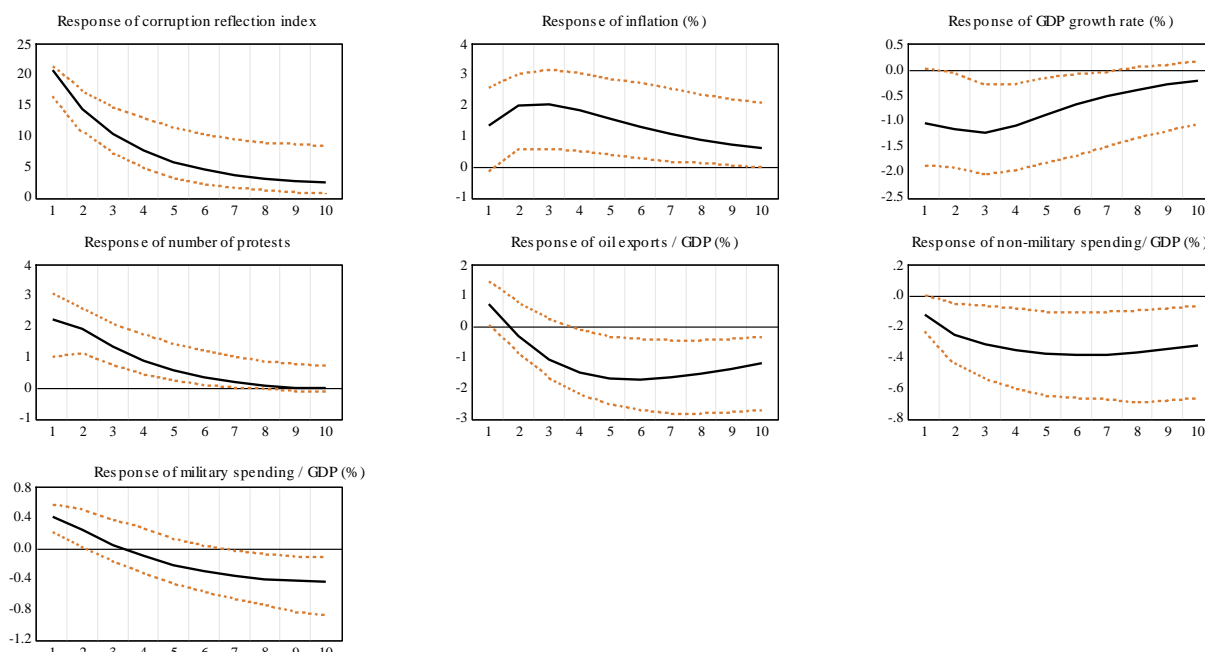

Figure 4. Responses to Cholesky one standard deviation positive shock in corruption reflection index of Iran

Note: the solid line shows the responses to a shock in corruption. The dashed lines show 68% confidence intervals based on Killian bias-corrected bootstrap interval. Horizontal axis shows the years after the initial shock. The vertical axis shows the magnitude of the response.

Note: the solid line shows the Generalized responses to a shock in corruption. The dashed lines show 68% confidence intervals based on Killian bias-corrected bootstrap interval. Horizontal axis shows the years after the initial shock. The vertical axis shows the magnitude of the response.

In Figure 6, we have summarized the significant responses of protests to positive shocks in key variables (corruption, economic growth and military spending share in GDP).

Figure 6. Response of protest variable to shocks in relevant variables

Response to Generalized One S.D. Innovations

68% CI using Kilian's unbiased bootstrap with 999 bootstrap repetitions and fast double bootstrap approx.

Finally, we also show that the positive response of the protest variable to a positive shock in the corruption reflection index remains statistically significant at higher levels of confidence of 90% and 95% levels.

In Figure 7, we show the response of protests to corruption at levels of 90 and 95% levels of confidence.

Response of protest to corruption Generalized One S.D. Innovation
95% CI using Kilian's unbiased bootstrap with 999 bootstrap repetitions and fast double bootstrap approx.

4.2. Variance decomposition

In this section, we decompose the fluctuations of protests that arise from shocks in other variables, including the corruption reflection index in the VAR system. In other words, we explain the fluctuations in protests that are explained by fluctuations in other variables. A higher share of explanatory power will indicate a higher weight of that shock in predicting the variance of protests. The results are shown in Table 5.

The results show that after variation in the protest variable itself, which explains between 60-70% of its variance, the corruption reflection index is the most important variable. In the first year after the shock, the corruption index explains 11% of the fluctuations in protest and increases to approximately 21% by the fifth year after the shock, remaining at this level by the 10th year. The next important variable to predict the fluctuation of protests is the economic growth rate. This variable explains 8 to 10% of the fluctuations in the short and long term. Fluctuations in inflation has a more moderate power (about 5%). Military and non-military spending and oil export revenues have no explanatory power for protests in the first year after the shock. Their importance remains low in the long term.

Table 5. Variance decomposition of protests

| Period after shock | Corruption | Inflation | GDP growth | Protests | Oil export /GDP | Non- military spending /GDP | Military spending /GDP |
|--------------------------|------------|-----------|---------------|----------|--------------------|--------------------------------------|------------------------------|
| 1 | 11.03 | 5.63 | 7.92 | 75.42 | 0.00 | 0.00 | 0.00 |
| 5 | 20.87 | 4.88 | 9.74 | 62.09 | 2.16 | 0.10 | 0.15 |
| 10 | 20.87 | 4.86 | 9.78 | 61.36 | 2.46 | 0.30 | 0.38 |

5. Conclusions

Our study introduces a new index for corruption reflection using media coverage in Iran for over the past 50 years. It is the first news-based index of corruption reflection in the case of Iran. We examine how protests in Iran, which is the sum of events under riots, strikes and anti-government demonstrations, are interconnected with corruption within the Iranian society, controlling for other channels. Our VAR model and its applied tools (impulse responses and variance decomposition analyses) show a robust effect of the corruption reflection index on protests. The response of economic growth to corruption in Iran is negative and we also show that the response of protests to a positive shock in economic growth is negative. Thus, one effect of corruption is to lower economic growth and reduce the opportunity cost of engaging in protests. Military spending also shows a positive response to corruption shocks. The militarization of the economy decreases non-military spending, lowering economic growth in Iran in our analysis. The response of protests to a positive shock in military spending is positive and significant in the short term. We also show that the inflation response to a positive shock in corruption is positive and significant. However, the response of protests to a positive shock in inflation is statistically insignificant.
