Abstract. This paper studies the firm-level short-term impact of one of the largest credit guarantee programs in the world recently implemented in Turkey. Using a combination of firm-level administrative databases of tax registry, credit registry, and the credit guarantee fund (CGF) registry, we analyze the characteristics of the CGF supported firms and the program's impact on their employment, sales, and credit default probability. We find that the CGF program on average had a positive impact on the performance of treated firms, where the CGF supported firms were able to increase their employment by 17 percent, sales by 70 percent and reduce their credit default probability by 0.6 percentage point relative to their matched-control group. Evaluating our estimation results at variable averages shows that every 1 million TL credit generated via the CGF program preserved 2.7 extra employment and stimulated about 3 million TL in sales. We also observe an overall increase in firm indebtedness, which may adversely affect firms' financial health in the long-run. Moreover, our findings reveal that the program impact is heterogeneous across firm size and sector groups. Using this heterogeneity, we perform counter-factual policy exercises indicating that redesigning the program with such priorities can bring substantial efficiency gains.

1 Introduction

Improving credit access of firms with resource shortages is a difficult policy question that is usually raised for small and medium-sized enterprises (SMEs). As bank debt remains the primary source of external finance for most SMEs in many countries, particularly the emerging ones, most public policy initiatives have consequently centered on bank lending. Traditional banking practices, generally placing strong reliance on hard information (e.g., reliable financial statements) and collateral capacity in risk assessment, limit SMEs' credit access. With a capacity to improve collateral capacity, public guarantee schemes have recently emerged as a popular policy tool in many developed and developing countries. Using a combination of firm-level administrative databases of tax registry, credit registry, and the credit guarantee fund (CGF) registry, we study the Turkish 2017 CGF program in this paper. More specifically, we first analyze the characteristics of the CGF supported firms and then study the program's impact on various firm performance indicators in the short-run. The Turkish CGF program implemented in 2017 was a unique experience. It stood out as the biggest guarantee program implemented globally in the same year with roughly 7.6 percent GDP share credit stimulus coverage that was roughly double the size of the second-largest guarantee program implemented in Japan in the same year (4 percent of the GDP).

Domestic credit markets in Turkey had been experiencing a tightening since the shrinking in global liquidity in 2013, which further toughened with the increase in domestic uncertainty due to the geopolitical developments in 2016. The credit growth was recorded to be negative along with the lowest GDP growth experienced in 2016 for the first time since the Global Financial Crisis (GFC) in 2009. To bring back the economy in 2017, the Turkish government implemented one of the biggest credit guarantee programs in the world that reached almost 20 percent of its total existing firm credit stock as of 2016. Using novel administrative databases, we analyze the firm-level impact of this giant program in this paper. We first analyze the differences between the CGF supported and non-supported firms' characteristics, including sector, size, and ex-ante risk distributions. Building on this background, we then match the CGF supported firms (the treatment group) with control firms based on their observable characteristics. Given our data's richness, we select the control firms based on revenue size, asset, capital and debt structures, exante riskiness, industry, and year. This level of detailedness of our data is rather rare in similar studies, which is essential to construct a reliable control group that will mostly determine the identification quality of the program impact. Using matched pairs, we then employ a Differencein-Differences (DiD) framework to provide an in-depth evaluation of the firm-level impact of the CGF program on the ex-post performance of the CGF supported firms in terms of employment, sales, and credit default probability.

We find that the CGF program created a significant redistribution of credits in 2017 towards smaller-sized firms (e.g., micro and SMEs) and particularly benefited wholesale and trade, manufacturing, and construction industries. In terms of their ex-ante risk attributes, we did not find any significant divergence between the CGF supported and non-supported firms. This is to say that we do not observe any statistically significant tendency towards allocating more CGF resources to risky firms given the government guarantees (i.e., moral hazard problem). More specifically, our findings show that the CGF program had substantial positive impact on firm performance in the post-program years. According to the results, the CGF supported firms on average preserved 17 percent more employment, generated 70 percent more sales, and experienced 0.6 percentage point less credit default than their matched pairs in 2018. Evaluating these estimates at their sample averages implies that an extra 1 million TL loan generated via the CGF program preserved roughly 2.75 more employment, generated about 3 million more sales, and reduced the average credit default probability by nearly 6.5 percent in 2018. These findings are robust to various checks, including additional controls and sub-sample considerations. Our findings also document that the program impact is heterogeneous across firm size and sector groups. In particular, the program's positive impact on medium-size firms is much larger than other size groups. On the sectoral heterogeneity, the CGF program is more effective in preserving employment in labor-intensive industries (e.g., service) and more effective in generating sales in sectors that serve more to the domestic economy (e.g., wholesale and trade). The manufacturing sector shows an intermediate case, where the employment and sales impact of the program is comparable. Our counter-factual analysis shows that substantial efficiency gains are possible by redesigning the program based on the program's size and sectoral impact heterogeneity.

We also provide further estimations on the program's impact on various firm asset types and liabilities. The results indicate that the program's positive impact on long-term assets (e.g., intangible assets such as R&D) appears to be weaker compared to short-term assets (e.g., inventories). This is perhaps expected given the original purpose for expanding the CGF program in 2017 that was to mitigate the temporary negative impact of the geopolitical developments of 2016. In that regard, the program seems to be successful in reversing the domestic economy's negative trend to positive by empowering firm performance through large liquidity injection. However, considering its weaker support for firms' long-term growth perspectives, the CGF program may be complemented with other government programs aiming to support productive capital, including investment subsidies and incentives. An increase in overall firm indebtedness due to the CGF program is also evident from our results, which may adversely affect firm credit default probabilities in the long-term. This is especially the case for micro firms, as our results show that the CGF supported micro firms experienced an increase in their credit default probability in 2018. Monitoring firms' indebtedness and ensuring appropriate debt management practices through mentoring services can significantly mitigate long-term credit default risks.

Over the last two decades, credit guarantee schemes (CGS) are being expanded in size and volumes in many countries (OECD, 2019). Therefore, the economic impact of credit guarantee programs has been examined in a variety of theoretical and empirical studies; however, no consensus exists among researchers. One strand of theoretical literature suggests that credit guarantee programs may reduce credit rationing under asymmetric information à la Stiglitz and Weiss (1981) and result in funding profitable projects that would not be realized without government intervention (Mankiw, 1986; Gale, 1990, 1991). Another strand in the theoretical literature

suggests that government intervention may increase information problems and worsen credit conditions (Chaney and Thakor, 1985; Aghion and Bolton, 1997). However, firm-level credit guarantee scheme evaluation literature is brief and to the point. In pioneer papers, Instrumental Variable (IV) and DiD methods are often used. For example, Kang and Heshmati (2008) used IV and OLS methods for the Korean program KOTEC, one of the largest CGS globally, and found that the scheme partially improved loan availability and employment level of the firms. Zecchini and Ventura (2009) applied DiD for Italian data and confirmed that the credit guarantee program leads to higher leverage and lower debt cost for firms. In France, Lelarge et al. (2010) assessed the SOFARIS program's impacts using OLS and DiD methods and found positive effects of the program on firm growth, external finance availability, and negative effect on interest payments in the newly created firms.

In the last decade, other causal inference methods such as Propensity Score Matching (PSM), CEM, and Regression Discontinuity Design (RDD) are integrated into existing methods. In that respect, Hancock et al. (2007) employed state-level US data for the period of 1990-2010 and found that Small Business Administration (SBA) loans had a positive impact on employment, but the impact on firms' default probability was moderate. Hancock et al. (2007) also found that SBA programs helped stabilize the economy by offsetting the slowdown in business and the financial sector's capital pressures. Uesugi et al. (2010) applied the PSM method for Japanese credit guarantee programs and emphasized progress in credit availability. Uesugi et al. (2010) also showed that banks' financial structure is important in liquidity persistence. Ono et al. (2013) used PSM and found that although Japan's Emergency Credit Guarantee Program significantly improved credit availability for SMEs, there was no significant impact on investment, employment, or profitability. De Blasio et al. (2014) used RDD techniques for Italy and found that the Fondo di Grazia program's loans had no impact on investment and interest rate charged by the banks and mixed impact on sales. Moreover, their results suggested that the program decreased the loan repayment likelihood of eligible firms. Using firm-level data drawn from fiscal receipts over the years 1992–1999, Bach (2014) estimated the effect of eligibility for the CODEVI program, the French loan guarantee program, on bank finance availability with a DiD approach. Bach (2014) found that the program substantially increases debt financing without substitution between subsidized and unsubsidized finance while returns on subsidized debt are significantly above its market cost. He also found that the program did not cause a surge in default risk. Brown and Earle (2017) analyzed linked databases on all SBA loans and lenders and on all U.S. employers to estimate the impact of access to finance on firm-level employment growth. They employed PSM methodology and used fixed effects and IVs based regressions. They showed that, on average, 3-3.5 jobs were created for each million dollar loan supplied via the SBA program. Their results also suggested that estimated impacts were stronger for younger and larger firms. More recently, Bertoni et al. (2019a) used PSM and IV-2SLS to study a sample of 512 entrepreneurial ventures that received a government-sponsored participative loan from a Spanish government agency between 2005 and 2011. Bertoni et al. (2019a) found evidence that government-sponsored participative loans significantly boosted the beneficiaries' employment and sales. Similarly, Bertoni et al. (2019b) investigated the economic effects of guaranteed loans granted under the EU programs MAP and CIP in Italy, the Benelux, and the Nordic countries from 2002 to 2016 using the CEM and PSM. Bertoni et al. (2019b) found that guaranteed loans positively affect the growth in assets, sales, employment, and the share of intangible assets. Using the PSM estimator and the DiD regressions on a sample of 38,000 Italian SMEs in the period 2007-2009, Caselli et al. (2019) showed that the magnitude of the effect varies across firm sizes and sectors, where micro-and small-sized firms benefit more from the support of the Central Guarantee Fund in Italy.

The remainder of the paper is organized as follows. In Section 2, we present the functioning and evolution of the Turkish CGF. In Section 3, we briefly describe our data and present the main databases. In Section 4, we discuss the main differences between the CGF supported and non-supported firms in terms of their size, sector, and risk profile, as well as the construction of our risk assessment model. Section 5 discusses the impact analysis, including the details of our identification strategy and our estimation results. We present several robustness checks along with the potential caveats in evaluating our results in Section ??. Section 7 presents further extensions of our main estimates. Finally, Section 9 concludes.

2 Institutional Background

The CGF was established in 1991 as a state-funded program with the primary mandate of improving credit access conditions for SMEs. The CGF operates as a joint-stock company, shareholders of which include chambers, non-government organizations, banks, and public agencies.¹ The CGF issues guarantees via bank loans either through its equity or through the Treasury support funds. In doing so, the CGF provides a guarantee for borrowers, aiming to improve borrowers' collateral quality and to reduce the damage on lenders in the case of default. In other words, CGF acts as a guarantor for credit-constrained firms that face difficulty in obtaining loans due to insufficient collateral. With the CGF guarantees, firms, particularly SMEs, can better access credit at a lower cost and longer maturities. The low-risk nature of CGF backed loans also brings certain benefits for the loan issuing banks, allowing them to share their credit risk and strengthen their regulatory capital. The risk weight² for the CGF backed loans is usually close to zero or at least lower than non-CGF backed loans, which supports the issuing banks' capital adequacy ratio. In what follows, we discuss the development of the CGF program and discuss its recent policy context in Turkey.

The tightening in global liquidity following the Fed taper tantrum policy in 2013 sharpened the decline in credit growth, particularly in FX, in the Turkish domestic credit market (Figure 1). In addition to this global tightening, Turkey experienced a severe geopolitical shock in 2016. The shock increased domestic uncertainty and further tightened the domestic credit conditions (CBRT, 2016). Real credit growth was recorded to be negative in 2016 for the first time since the

¹CGF is exempt from corporate tax and value-added tax in its transactions for providing loan guarantees. ²The risk weights are determined by the Banking Regulation and Supervision Agency (BRSA) of Turkey.

GFC in 2009. The negative credit growth was apparent in both FX and TL credits in this year. Given the high reliance of Turkish industries on credit finance (Akcigit et al., 2020), the annual real GDP growth recorded the lowest rate in 2016 since the GFC, although it remained positive. Many firms experienced an instant slowdown in business, while the financial sector's credit issuance appetite was rather low. To restore expectations and avoid a potential risk of a sudden stop in the economy, the Turkish government provided significant liquidity to the markets via the CGF program by multi-doubling its size in 2017. With the implementation of the CGF program in 2017, we observe an instant reversal in TL credit growth, while FX's negative trend continued.³ Moreover, the real GDP growth in 2017 bounced back to 7.5 percent.

Figure 1: Real Annual Credit Growth Contribution by Credit Denomination and Real GDP Growth

Source: Authors' calculation from the CR and Turkish Statistical Institute (TSI) databases. Notes: The figure shows the real annual credit growth contribution by credit denomination and real GDP growth over the last decade.

Until the end of 2016, CGF had mostly run on a small scale and issued credit guarantees only from its limited equity. In December 2016, the Turkish Treasury signed the first protocol with the CGF to increase its guarantee capacity up to the first 20 billion TL, which was then further upgraded to 250 billion TL in March 2017 with additional protocols.⁴ Smaller scale packages

³ Most of the CGF backed loans were issued in TL – i.e., the share of CGF backed TL loans in 2017 was about 85 percent, and the remaining 15 percent was denominated in FX – the CGF program seems to be successful in reversing the negative trend in especially TL credit growth. However, high volatility in TL during these years would also add to the negative growth in FX credits and hence, might have contributed to the instant increase in TL credit growth.

⁴With the new protocols, some of the tighter conditions in the earlier protocols were also removed. For instance, the condition that the beneficiary firms must not have outstanding non-performing loans (NPLs) in the regulation was also relaxed in this package. Credits in Turkey are classified into five groups, where the first two groups are performing loans, and the last three groups are non-performing loans with at least 90 days and more overdue loan payments. The new regulation allowed only the firms with 3^{rd} and 4^{th} group NPLs to apply for the CGF program, while the last group would still not be allowed to benefit from the program. The details of the current NPL definitions in Turkey can be found in decree numbered 29750 in the Official Gazette dated 22/06/2016, and the details of the

continued to be implemented in the following years; however, the 2017 package has been the biggest guarantee program not only in the history of Turkey but also in the world. Figure 2 summarizes the official numbers for the CGF program in Turkey. While the number of credit issuance and volume were tiny before 2017, there was a significant expansion of the program in 2017. The CGF program of 2018 was also important, but it was not comparable to the program's size in 2017. Hence, the current study focuses on the evaluation of the CGF program in 2017. Figure 2: Size of Credit Guarantee Fund

Source: CGF Activity Report in 2018.

Notes: The number of credits issued represents the total number of credit issuance, including multiple credits by any firm.

The CGF expanded its operational capacity in 2017 by using two separate streams of assessment procedures for guarantee issuance: the portfolio guarantee system (PGS), and the portfolio limit system (PLS). Under the PGS, the SME group guarantee limit was 12 million TL, and the group limit for large firms was 50 million TL.⁵ The PLS, on the other hand, was designed specifically for large firms where the group limit was 250 million TL. Under the PGS, banks followed their internal credit risk assessment⁶ and the CGF authorities did not make an additional risk assessment, while under the PLS, the CGF authority also undertook its risk assessment in order to make a final decision on the guarantee application. Moreover, the CGF followed a different guarantee coverage for different firms, based on their size and export status. The guarantee coverage in the 2017 program was 90% for SME loans, 85% for large firm loans, and 100% for exporter loans. Details of the 2017 CGF program are summarized in Table 1.⁷

CGF program regarding the NPL classification can be found in decree numbered 9969 in the Official Gazette dated 10/03/2017.

⁵Limits were imposed on the company holdings or groups, not on individual firms. Basically, there was one global limit for the group company, and the total lending to firms within the same group could not exceed the global limit.

⁶Banks in Turkey follow Basel requirements in terms of their risk assessment methodology that must also be approved by the regulatory agency, BRSA.

⁷For a more detailed discussion on the CGF program design, see CBRT (2017).

Characteristics	PGS	PLS				
Total Guarantee Limits	12 million TL for SMEs 50 million TL for large firms	200 million TL for large firms				
Risk Assessment	Based on banks' internal risk assessment	In addition to banks' internal assessment, CGF also conducts its risk assessment				
Assessment Duration	Final assessment completed in 2 days	No duration limit on assessment				
Maturity	For working capital loans: maximum 5 years, with a grace period of maximum 1 year For investment loans: maximum 10 years, with a grace period of maximum 3 year.					
Guarantee Coverage	For SMEs 90% , for large firms 85% and for exporters 100%, of the total loan amount					

Table 1: Main characteristics of the CGF program in 2017

Source: CGF.

The moral hazard problem is a potential challenge for guarantee programs in general (Boot and Thakor, 1994; Aghion and Bolton, 1997). In order to avoid moral hazard problems, the CGF program of 2017 imposed an additional limit on each issuing bank's non-performing loan (NPL) rate of its CGF portfolio. This is to say that the Turkish Treasury will pay off the non-performing CGF balance based on the guaranteed schedule as long as the issuing bank's CGF portfolio NPL rate remains below 7 percent. If a bank's NPL rate of its CGF portfolio exceeds 7%, then the bank has to bear the remaining credit risk fully. Regarding the fee and commission expenses, the issuing bank demands a one-off guarantee commission from the beneficiary firm at a rate of 0.03% of the guarantee amount for each guarantee payment at the time of a letter of guarantee requested. Moreover, the bank cannot charge any additional fees other than the costs to be paid for procedures to be performed by third parties (e.g., appraisal, insurance, etc.) and the one-off guarantee commission to be paid to the CGF.

Overall, following the geopolitical shocks in 2016, the CGF program was used as a restoring policy device to provide liquidity to the domestic credit market in 2017. The program seemed to have achieved significant ease in domestic credit conditions given that the real credit growth for all firm size and sector groups bounced back to high positive rates in 2017 from high negatives in 2016. More specifically, SMEs appear to have particularly benefited from the program given the high positive real credit growth rate recorded in 2017, which came after a credit tightening period since 2013. Similarly, the manufacturing sector, which had been experiencing a severe reduction in credit growth since 2013, especially experienced a significant easing in credit access in 2017.

3 Data

We utilize several administrative databases that are made available to the CBRT by the relevant government bodies. These are Firm Tax Registry (FTR) of the Treasury and Finance Ministry, Credit Registry (CR) of the Banks Association of Turkey, and the Credit Guarantee Fund (CGF) database. FTR contains yearly balance sheets and income statements for virtually all Turkish firms, both private and state-owned, from 2006 until 2018, which is the most recent year available.

We only focus on the non-financial private legal entities (e.g., incorporated businesses) in the FTR, where we exclude the finance and public sectors and the unincorporated business (i.e., sole-proprietorship or partnership businesses). CR records all credit institutions' exposures to Turkish firms monthly, providing detailed information on all firm-bank credit relations. The CGF database records all firm-level credit information in 2017 at a monthly frequency. We discuss further details of each data set below.

3.1 Tax Registry

We use balance sheets and income statements of only the non-financial private legal entities in the analysis, given that most unincorporated businesses only report simplified tax records.⁸ The raw administrative data was initially revised by the Turkish Statistical Institute (TSI), especially with respect to firm sector classifications to ensure the quality of sector identifications. The TSI also provided firm-level employment data that was originated from the social security records. Moreover, legal entities cover most SMEs and all of the large firms, and some of the micro firms. Among legal entities, we exclude firms that reported incomplete or incoherent data from the analysis, such as observations with negative fixed assets, negative current assets, negative total assets, and negative net sales. We also impose a one percent winsorizing on each of these variables at a given year and NACE Rev-2 digit sector level in the analysis.

3.2 Credit Registry

Credit Registry provides further details of all firm-bank credit relations, including type, maturity, currency denomination of all the credit relations, as well as, lending institution branch level information. We use credit registry in the analysis mainly for two purposes: first, we obtain non-CGF firm-bank credit relations in 2017 and 2018, and also, the credit distributions in other years outside 2017. Second, we utilize the CR database to develop a risk scoring tool to measure firm riskiness. The critical variable we compiled from the CR database is the default event – i.e., defined as the existence of 90 days overdue loan payment (e.g., non-performing loans (NPL)) for each firm in a given year. We also use several other characteristics of firm-bank credit relations, such as the age of credit relation, the number of bank relations, and credit default history in estimating risk scoring.

3.3 Credit Guarantee Fund Registry

The CGF registry contains information on all the firm-bank level guaranteed credit transactions, including loan size, maturity, bearing interest rate, location, and guarantee level issued under the CGF program. We specifically use the information on the beneficiary firm, loan amount,

⁸The vast majority of unincorporated businesses operate under simplified tax regimes and thus, are not obliged to report regular balance sheets and income statements for tax purpose.

and issuance date from the CGF database in the analysis. About half of the firms that benefited from the CGF program in 2017 were unincorporated businesses, although their volume is only about 10.2 percent of the CGF backed loans in 2017 (Figure 3), which is similar to their average share in total firm credits (10 percent according to the credit registry) in 2017. The vast majority of the CGF back loans were issued to legal entities by volume that correspond to 90 percent of the program. Further breakdown of these figures by sector is presented in Figure 4. The figure shows that the share of unincorporated businesses in terms of volume is less than 16 percent in all sectors, except in agriculture & mining. This is mainly because most of the firms, especially in agriculture, are family businesses owned by farmers. Our coverage of this sector by volume is about 58 percent. Moreover, more than 70 percent of the CGF supported firms in the construction, energy, and manufacturing sectors are legal entities and thus, covered in the analysis. The share of the CGF supported legal entities in the service, tourism, and wholesale and trade sectors is above 50 percent. Our sample coverage of the CGF supported firms in the agriculture & mining sector is only 15 percent.

Source: Authors' calculation from the CGF database.

Figure 4: CGF Credit Distribution by Firm Type and Sector

Source: Authors' calculation from the CGF and FTR databases.

Overall, we focus on legal entities in the study, which implies that our sample covers about 52 percent of the CGF supported firms and 88 percent of the CGF backed loans in 2017.

4 How Different are the CGF Supported Firms?

We first provide a descriptive analysis on the distributional comparisons of the CGF supported firms to those not supported under the CGF program (non-CGF firms). In particular, we show distributions of the CGF and non-CGF loans by firm size, sector, and risk groups. To establish ex-ante risk scores, we also develop a risk scoring model following the relevant literature.

4.1 Size and Sector Distributions

We present and discuss the size and sector distributions of our final CGF data in this section. To make comparisons, we also present the same distributions for average total lending between 2013 and 2016 and non-CGF loans in 2017, as benchmarks, in Figure 5. More specifically, Panel (a) of the figure displays the size distributions, and Panel (b) shows the sector distributions. The CGF program seems to increase credit access of micro, small and medium-sized firms, given that the CGF credit shares of these size groups were much higher than the presented benchmarks. Moreover, large firms received a smaller share of CGF backed loans relative to their benchmark shares. Their share of the CGF backed loans in 2017 (45 percent) was much smaller compare to their share of non-CGF loans in 2017 (75 percent) and to the share of credits in earlier periods (on average higher than 70 percent). The CGF program clearly achieved a redistribution of credits

from large firms towards SMEs.

Figure 5b also displays the sectoral distributions of the CGF backed loans and relevant benchmarks. The CGF backed loan shares of the manufacturing, tourism, and wholesale and trade sectors appear to be higher than their shares from non-CGF loans in 2017 and from loans issued in the pre-CGF period (between 2013 and 2016). In contrast, services and energy sectors obtained much smaller shares from the CGF program than the benchmarks.⁹ The remaining two sectors, agriculture & mining and construction sectors, received similar shares from the CGF program to their general benchmarks. Overall, the CGF program seems to induce a moderate credit redistribution towards manufacturing, tourism, and wholesale and trade sectors.

(b) Loan Distribution by Sector

Source: Authors' calculation from the CGF and CR databases.

Notes: Each column in (a) shows the share of credit (CGF and Non CGF) given to each size group, excluding the non-matched CGF supported firms. Each column in (b) shows the share of credit (CGF or Non CGF) given to each sector. Agr. & Mining represents the agriculture & mining sector.

Figure 6 presents credit concentration by firm size percentiles where the firm size is measured by total assets. As before, we also present the same distributions for average total lending between 2013 and 2016, and non-CGF loans in 2017 in the same figure as benchmarks. The figure shows that the CGF backed loan distribution is more skewed towards relatively smaller size firms, which implies granting greater credit access to micro and SMEs.

⁹This is perhaps because firms in the energy sector tend to demand more FX loans than TL, while the CGF program mainly provided TL liquidity. According to the Credit Registry, as of December 2016, roughly 90 percent of the energy sector's outstanding credit balance is in FX.

Figure 6: Credit Concentration by Firm Size

Source: Authors' calculation from the CGF, FTR, and CR databases.

Notes: Panel (a) presents the cumulative distribution of credit share with respect to the firm size based on the total asset. Panels (b) and (c) show the credit share of each size percentile for small (below 50th percentile) and large firms (above 79th percentile), respectively.

4.2 Ex-Ante Risk Distributions

As briefly discussed above, the moral hazard problem is a potential challenge for guarantee programs in general (Boot and Thakor, 1994; Aghion and Bolton, 1997), where the participating lending institutions may also consider issuing credits to risky borrowers given the state guarantees. CGF programs generally include various check-and-balance conditions, as done in the Turkish case, which included certain credit worthies and payback capacity of borrowers, as well as NPL limits on the lending institution's CGF backed loan portfolio. However, it is still worth investigating how sufficiently these conditions ensure the CGF credit portfolio risk remains at acceptable levels. Given our data's richness, we first develop a scoring tool to assess ex-ante firm credit default riskiness. Using these scores, we then present ex-ante credit default risk distributions for the CGF supported and non-supported firms in 2017.

The risk scoring tool follows the related credit risk scoring literature (e.g., Antunes et al., 2016 and Martinho and Antunes, 2012), where we employ a simple logit model to estimate the ex-ante probability of default (PD). The default event is defined as past-due payment of more than 90 days on any credit obligation in a given year, which coincides with the Basel II default definition. We first construct firm-level financial history data from the CR database to estimate the default probabilities, containing a panel of firms with credit default and credit relation history between 2006 and 2017. We also construct a second-panel data set on firm characteristics and a set of performance indicators using FTR for the same period. We then match the two data sets using firms' tax identifiers. To capture ex-ante risk scores, we regress firm default status in t + 1 over financial history and non-financial firm characteristics (e.g., several balance sheet ratios such as leverage, liquidity, etc.) in t. The model predicts firm risk scores in t + 2 (that is unknown

at time t + 1) by applying the estimated coefficients to firm controls in t + 1.¹⁰ Our purpose of focusing on ex-ante risk scores – rather than directly looking at firm default status in 2017 – is to control for the risk assessment of firms from creditors' perspective, as firms' default status in 2017 was unknown in 2016, where creditors had to act based on their risk assessments. With this approach, we can also control for creditor (mis)behaviors, such as lending–tendency towards more risky firms under the CGF program given the state guarantees.

After predicting risk scores for firms in our sample, we divide scores into percentiles, from the lowest to the highest, to show the total amount of credit issued to firms in each risk-percentile group. When firms are ranked according to the risk groups, we observe that the credit distributions of 2017 do not show a significant difference either between the CGF and the non-CGF loans, or compared to previous years, namely the 2013-2016 average, in terms of ex-ante credit riskiness (Figure 7). The only difference between the CGF loans and the rest seems to be the coverage of around-zero risky firms, which tend to be the largest firms in the economy. Given the CGF program's lower coverage of large firms, it has a relatively broader coverage of firms in the second-lowest decile (i.e., from 10th to 20th percentiles). Moreover, there appears to be a clear negative relationship between risk score percentiles and credit share that would be expected in a regular risk management framework. Considering these results, we conclude that creditors have no prior systematic selection, such as pushing relatively riskier firms among the legal entities to be under the CGF program.

¹⁰This is a classical approach in firm scoring that is also used by many financial institutions in accordance with Basel requirements. The main point of ex-ante risk scoring comes from the fact that, for instance, banks did not have firm balance sheets of 2017 when firms applied for the CGF program in 2017. Therefore, banks had to run their risk models with default events in 2016 on firm characteristics in 2015, and then, with the predicted coefficients and balance sheet information of 2016, banks can assign risk scores to firms for 2017. Further details of our risk scoring methodology, including data, variable selection, estimation, and performance evaluation, are presented in the Online Appendix.

Figure 7: Credit Risk Distribution

5 Impact Analysis

In the second part of the analysis, we estimate a conditional difference-in-differences model whereby we first match each treated firm with a control firm. As the CGF provision was not a random process, rather subject to several layers of screening by the credit-issuing banks and the CGF regulations, implementing the estimation without matching would produce bias results. In what follows, we first explain the details of our matching methodology and then present our estimation strategy. We conclude the section with a detailed discussion of our estimation results.

5.1 Matching: Establishing a Control Group

Following the initial cleaning, our sample of legal firms, receiving loans via the CGF program (the treatment group), reduces to 86,000 observations in 2017. Given that we have access to the entire population of legal firms that existed in the same years, we have a large sample for selecting our control group. In the matching, we require both treatment (i.e., the CGF supported) and control (i.e., non-supported) firms to exist in both years, 2016 and 2015.¹¹ We conduct one-to-one matching using the coarsened exact matching methodology of Iacus et al. (2012) with no replacement. The matching is implemented based on observable firm characteristics, including

Source: Authors' calculations from the CR, FTR databases, and estimated PDs. Notes: The figure presents the credit risk distribution by credit type. Flow credits are calculated by consolidating the bank-firm-level new loans on a monthly basis for each year by using the CR database.

¹¹In an alternative sample (henceforth *Sample 2*), we also included firms that existed only in 2016, not in 2015.

total assets, tangible assets, financial debt (i.e., outstanding credit balance), and total sales in 2016 and 2015. Additionally, we also employ predicted risk scores, developed in Section 4.2, in the matching to control for firms' ex-ante riskiness in 2016. Main sectors are preserved in the matching.¹² In each variable, we employ 10 groups.¹³ We present the summary statistics before and after matching in Tables 2 and 3, and the balancing test results for the variables used in the matching are shown in Table 4.

		2015	5-2016		2017-2018

Table 2: Summary Statistics (Treatment Firms and the Rest) Before Matching

Notes: N denotes the number of firms. The mean values (in TL for monetary variables) in the table are annual averages. All variables except risk scores and default are in logarithmic form. Default is one for firms with non-performing loans and zero otherwise.

Tables 2 and 3 show summary statistics of the key variables before and after the matching, respectively. Table 2 shows that the CGF supported firms are relatively larger in assets, sales, and employment. Their financial debt (i.e., outstanding credits) is larger with relatively lower risk scores. However, after matching, most differences significantly reduce, Table 3. Asset size, sales, employment, credit balance, and default probability are merely the same in the matched sample in the pre-2017 years. Expectedly, we observe differences between the two groups in 2017 and 2018 that will be further explored in the following section.

¹²Main sectors are agriculture and mining, construction, energy, manufacturing, services, tourism, and wholesale and trade.

¹³With the exceptions of predicted risk score (default probability) that is employed with five groups, and total sales that is employed with 20 groups in 2016 and 10 groups in 2015. This differentiation in the number of groups is just for improving the matching quality.

Table 3: Summary Statistics (Treatment Firms and the Rest) After Matching

Notes: N denotes the number of firms. The mean values (in TL for monetary variables) in the table are annual averages. All variables except risk scores and default are in logarithmic form. Default is one for firms with non-performing loans and zero otherwise.

According to Table 4, the initial bias between the treatment and the control groups is significantly reduced by our matching. In particular, we either obtain statistically insignificant mean difference test results for the difference between the CGF supported (treatment) and nonsupported (control) firms, or the test statistics dramatically declined along with an above 97 percent reduction in the percentage bias. In the base sample, we have ended up with 63,750 matches.¹⁴ In addition to the variables used in the matching, we also report balancing test results for two other main variables that were not employed in the matching; total liabilities and employment.¹⁵ After the matching, we also observe a significant reduction in the bias for these variables.

¹⁴In the alternative sample, *Sample 2*, where we also included firms that only existed in 2016, our sample reached to 67,446 matches.

¹⁵In the matching, we used financial debt and total sales instead of total liabilities and employment.

Table 4: Matching Performances: Balancing Tests for Treatment Firms and Matched Control Firms

Notes: N denotes the number of firms. All variables except risk score (PD) are in logarithmic form.

For further inference, we also present full distributions of total assets (a stock variable) and total sales (a flow variable) for the treatment and control groups in 2016 with samples before and after the matching in Figure 8. As an outside-matching criteria variable, we also present the same distributions for total liabilities. The distributions visually emphasize the quality of our matching, where the pairs almost entirely overlap.¹⁶ Distributions of the variables before and after the matching in only one year does not provide much information for the trends outside the years used in the matching. We therefore display the trends for total assets, total sales, and total liabilities in the panels of Figure 9 in years between 2006 and 2018.¹⁷ After the matching, our treatment and control groups, on average, follow similar trends until the CGF program implemented in 2016.

¹⁶Distributions of all other variables, used in the matching, present a similar picture and hence, not reported here. They are nevertheless available upon request.

¹⁷Trends of all other variables, used in the matching, present a similar picture and hence, not reported here. They are nevertheless available upon request.

Figure 9: Matching Performance: Trends

Source: Authors' calculation from the CGF and FTR databases.

5.2 Estimation: Difference-in-Differences Analysis

Using the matched sample, we estimate the following regression equation:

$$y_{it} = \alpha treat_i * post_t + \beta post_t + d_t + pair_i + sector_i * d_t + region_i * d_t + e_{it}$$
(1)

where subscript *i* denotes firm and *t* denotes year. The outcome of interest, y_{it} , covers various firm performance measures, including employment, sales, and credit default. All the dependent variables are in log levels, except the credit default that is a binary variable (i.e., one for firms with 90 days overdue credit payment; otherwise, zero). We implement two different timing specifications: very short-run and short-run. The very short-term results account for the program's impact only in 2017, which is presumably less than one year. As some significant portion of the CGF guaranteed loans were issued in the first four months of 2017, the program is expected to have some initial impact in the first year.¹⁸ The short-term results show the program's impact in a relatively longer time horizon, from the control year, 2016, to 2018. The implied impact of the program in 2018 would thereby account for the program impact in roughly one and half year time horizon. More specifically, in the first specification, *post*_t, the post-policy variable is one for 2017; otherwise, it is zero for the control years 2016 and 2015. In the second specification, *post*_t is equal to one for 2018 and zero for 2016, where we employ only the two years in the specification to capture the program's effect in a longer time horizon.

In both specifications, the treatment variable $(treat_i)$ takes the value of one if the firm received CGF backed loan in 2017, otherwise zero. $pair_i$ is a fixed effect identifying each matched pairs, treated firm, and its matched control. In an alternative specification, we control for firm fixed effects instead of pair fixed effects, in case our comprehensive matching methodology leaves out some non-random time-invariant variation between the treatment and control groups. We also control for time dummies and their interactions with industry and province to account for time varying common sectoral or provincial level shifts (e.g., demand shifts) in all specifications. The parameter α is our coefficient of interest, which shows the impact of receiving CGF backed loan in 2017 on the firm performance in 2017 and/or in 2018 relative to the control group. In addition to the binary treatment, we also estimate the model with continuous treatment, whereby the treatment is changed from a binary (i.e., zero/one) variable to a continuous one. In a nutshell, the binary treatment is multiplied by the CGF backed loan amount (in logs) in the respective years. More specifically, in the first specification (i.e., very short-run), the continuous treatment is the CGF backed loan amount received in 2017. However, in the second specification (i.e. shortrun), the continuous treatment is the sum of the CGF backed loans received in 2017 and the additional loans in 2018.

During the CGF program years, regular credit operations outside the program continued. This implies that some firms have also received other loans besides the CGF program, given that

¹⁸See Online Appendix for further details on the monthly distributions of the program

the program has balance limits and relatively lower coverage of certain credit types.¹⁹ To account for this, we test the robustness of our main estimates to controlling for non-CGF loans received in respective years. Excluding this control may overstate the CGF program's impact, as both loan types will provide support for firm activities and thus, would be expected to affect firm performance.

In principle, firms may utilize their CGF backed loans in 2017, while some firms may continue to use their approved credit line (with CGF support) or apply for new credit in 2018, as the CGF program continued to run in 2018. However, given the aim of this paper is to evaluate the impact of the largest CGF program, which was implemented in 2017, we only keep the firms receiving CGF backed loans for the first time in 2017 and may continue to use their credit lines or apply for a new one in 2018. In other words, we exclude firms that receive CGF support for the first time in 2018. Moreover, our main sample requires firms to survive in the post-treatment years, as exiting firms do not report financial documents, and thus, drop out of the sample. However, we relax this condition by imputing zeros to exiting firms' performance indicators in the robustness section. Secondly, in the credit default estimations, we exclude firms (and their matched pairs) with outstanding NPL balance before receiving CGF support. Dropping these firms from the credit default estimation sample ensures that the matched firms have similar ex-ante risk profiles and no default history before the treatment.

5.3 Results: Difference-in-Differences Analysis

Our estimation results are displayed in Tables 5 and 6. Each table has two panels: the very short-term (Panel A) and the short-term (Panel B) impact of the program. Results in each panel are reported for employment, total sales, and firm credit default. The binary and continuous treatment results are presented in separate tables.

The columns (1) – (3) of Tables 5 and 6 present the results for the impact of the program on firm employment. According to the results, the CGF supported firms, on average, preserved more employment than their pairs in the treatment years. This effect is statistically significant and consistent across different specifications. According to the baseline estimates in Column (1), the CGF supported firms preserved 15.8 percent more employment in the very short-run relative to their pairs (Panel A), while the magnitude of this effect slightly increases to 17.3 percent (Panel B) in the short-run. Controlling for non-CGF loans in the same years (Column (2) of both panels) reduces the magnitude of the CGF effect only marginally, while the statistical significance and economic importance remain strong. In Column (3) of both panels, we present the results with firm fixed effects (instead of pair fixed effects). Results remain consistent with only a marginal reduction in magnitude.

¹⁹For instance, the CGF program had lending limits, see Table 1, and also, lower coverage of FX denominated credits, see Footnote 3.

Table 5: The Effect of the CGF Program on Firm Performance: Binary Treatment

Notes: The table presents the regression results for the effect of the CGF program on firm performance in a binary setting. Each panel is a separate regression. Each column presents a regression of column heading on the variables listed in each panel. Columns 3-6-9 include firm fixed effect instead of pair fixed effect. The sector-time and province-time fixed effects are included in all specifications to control for overtime industry and province specific shifts. Robust standard errors in parentheses. All dependent variables except Default are in logarithmic form. *** p<0.01, ** p<0.05, * p<0.1. "Very Short-Run" covers the impact of the program only in 2017, while "Short-Run" covers the impact of the program in 2018.

Although the binary treatment results provide an overall picture of the program impact, they say little about the relationship between the CGF backed loan amount and firm employment. We explore this dimension in the first three columns of Table 6, where the treatment is now continuous. According to the very short-run results, a one percent increase in CGF loans preserved 0.012 percent more employment. The same exercise in the short-run, Panel (B), produces only a slightly higher impact, a 0.013 percent increase in employment. As before, controlling for the non-CGF loans and firm fixed effects does not change the main conclusion.

Table 6: The Effect of the CGF Program on Firm Performance: Continuous Treatment

Notes: The table presents the regression results for the effect of the CGF program on firm performance in a continuous setting. Columns 3-6-9 include firm fixed effect instead of pair fixed effect. The sector-time and province-time fixed effects are included in all specifications to control for overtime industry and province specific shifts. Robust standard errors in parentheses. All dependent variables except Default are in logarithmic form. *** p<0.01, ** p<0.05, * p<0.1. "Very Short-Run" covers the impact of the program only in 2017, while "Short-Run" covers the impact of the program in 2018.

The columns (4) – (6) of Tables 5 and 6 present the results for the impact of the program on firm sales. The results show that the CGF supported firms significantly increased their sales relative to their pairs. According to the binary treatment results, displayed in the respective columns of Table 5, the CGF supported firms on average increased their sales by 49 percent in the very short-run and 71 percent in the short-run. The continuous treatment results, presented in Table 6, implies a one percent increase in CGF loan support stimulated sales for 0.037 percent in the very short-run and 0.054 percent in the short-run. These results remain robust to controlling for non-CGF loans, as well as employing firm fixed effects instead of pair fixed effects.

The columns (7) – (9) of Tables 5 and 6 show the estimates for the impact of the program on firm credit default probability. The CGF program appears to reduce a firm's credit default probability in the very short-run, while the magnitude of the reduction fades in the short-run. More specifically, firms that are supported by the CGF program experienced a 3 percentage point less credit default in the very short-run relative to the control group. In the short-run, the impact reduces to 0.6 percentage point less credit default. Our results with continuous treatment show that a one percent increase in CGF backed loans leads to a 0.3 percentage point reduction in firm default probability in the very short-run and a 0.03 percentage point reduction in the short-run. Controlling for non-CGF loans or exploiting firm fixed effects only marginally changes the magnitude of the estimates, while the results remain qualitatively the same.

So far, the discussion provides a technical overview of the program impact, where evaluating the estimates at some reference values can bring a more intuitive understanding of the impact. All the reference mean values used in the evaluation are presented in Table A1. For instance, evaluating the short-run employment impact of the CGF program with binary treatment, 17.3 percent more employment (in the baseline specification), at the mean employment in 2016 (i.e., 29.4 employees) implies an average increase in employment for 5.1 workers in 2018. Considering the average total CGF backed loans per firm being around 1.9 million TL (i.e., loans received in 2017 and additionally in 2018), the implied monetary value for extra employment is roughly 370 thousand TL. Evaluation of the continues treatment estimates yield almost identical results for employment. Following the same approach and using baseline estimates from binary treatment, we present the average impact of a 1 million TL loan issued under the CGF program on employment, sales and credit default probability in Figure 10. According to the figure, an extra 1 million TL loan generated via the CGF program on average preserved 2.7 employment, generates 3 million in sales, and leads to a 6.5 percent decrease in average credit default probability in 2018.

Figure 10: Average Monetary Impact of CGF Supported Loans (per 1 million TL of CGF loan)

6 Breakdown of the Effect by Size and Sector Groups

In this section, we split our sample into size and sector groups to re-estimate our main specifications with different sub-samples. The firm size groups²⁰ are four, namely, micro, small, medium, and large, and the aggregate sectors are wholesale and trade, manufacturing, services, construction, tourism, energy and agriculture and mining.

6.1 Estimations by Firm Size Groups

Estimation results by size groups are displayed in Table 7. The results show that the medium firms appear to experience the largest impact on their employment relative to their pairs. On average, the CGF supported medium-sized firms recorded almost 20 percent more employment than their pairs. In contrast, the employment impact of the program appears to be the smallest among the large firms. The CGF program impact on sales is the largest among the CGF supported micro firms, while the magnitude of the impact on the CGF receiving small and medium-sized firms is similar. This is to say that the CGF supported micro-firms recorded about 81 percent higher sales than their pairs in 2018. This number is 70 percent for small firms and 71 percent for medium-sized firms. However, the CGF supported large firms experienced the least increase in sales, 35 percent, relative to their pairs. The CGF program impact on credit default varies across

Source: Authors' calculations. Notes: The figures present the average monetary impacts of receiving 1 million TL of CGF loan.

²⁰The size groups are determined based on the official definition for 2018 that is reported in Table A5.

size groups. On average, the CGF supported micro and large firms experienced a moderate increase in credit default probability in 2018 relative to their non-CGF pairs. On the contrary, the CGF supported SMEs recorded a reduction in their credit default probability relative to their pairs. In particular, the credit default probability for the CGF supported small and medium-sized firms is estimated to be 1.4 and 1.3 percentage points less than their pairs. These results are consistent across the three specifications.

Table 7: Short-Run impact of the CGF Program by Size Groups, Binary Treatment

Notes: Columns 3-6-9 include firm fixed effect instead of pair fixed effect. The sector-time and province-time fixed effects are included in all specifications to control for overtime industry and province specific shifts. Robust standard errors in parentheses. All dependent variables except Default are in logarithmic form. *** p<0.01, ** p<0.05, * p<0.1. "Short-Run" covers the impact of the program in 2018.

Figure 11 shows the implied impact of an extra 1 million TL CGF on employment and sales in Panel (a) and on firms' credit default probability in Panel (b). According to the figure, 1 million TL loan generated via the CGF program preserved the most employment (3.5 employment) and sales (3.8 million sales) among the medium firms, and it is the least among the large firms. An extra 1 million TL loan generated via the CGF program reduced credit default probability for small firms up to 30 percent (of the mean credit default probability in 2018 for small firms), while it increased the default probability for micro firms up to 45 percent.

Source: Authors' calculation from the CGF, FTR and CR databases.

Notes: In panel (a), the first bar shows the number of preserved employment while the second bar represents the amount of sales generated for receiving 1 million TL of CGF loan for each size group. In panel (b), each bar shows the percentage point change in default rate relative to the mean default rate by receiving 1 million TL of CGF loan. We follow the KOSGEB's definition for firm size.

In general, large firms are relatively less credit constrained than micro and SMEs, which may explain at least some of the heterogeneity in program impact across size groups. Therefore, extending new credit lines to large firms may not directly improve their credit access but rather substitute their non-CGF credits (Banerjee and Duflo, 2014). Some of the limiting attributes of the CGF program towards large firms, such as balance limits and favoring TL lending instead of FX, might have also contributed to this result. Considering their large scale, supporting large firms' credit access may be beyond the scope of CGF.

6.2 Estimations by Firm Sector Groups

The estimation results by sector groups are presented in Table 8.²¹ The table displays only the short-run impact results with the binary treatment specification. As usual, we present all the three specifications for each dependent variable separately in the table. The estimation results indicate significant differences across sectors. The CGF supported firms in the construction sector preserved 27 percent more employment than their pairs, while this effect for the remaining sectors is between 14 - 18 percent. In terms of sales, the CGF supported firms in the construction also recorded the highest increase relative to their pairs. Similar to employment, the CGF supported firms in the remaining sectors experienced an increase of a similar magnitude in

²¹As our sample coverage of energy and agriculture and mining sector firms is limited, we report the results for these sectors in Online Appendix.

their sales. Moreover, the CGF supported firms in the manufacturing and construction sectors recorded a significant reduction (around 1.25 percentage point) in credit default probability. The CGF supported firms in the wholesale and trade sector recorded a moderate reduction in credit default probability (0.5 percentage point) relative to their pairs. However, the impact is statistically insignificant in the remaining two service sectors, tourism and services.

Table 8: Short-Run impact of the CGF Program by Sector Groups, Binary Treatment

Notes: Columns 3-6-9 include firm fixed effect instead of pair fixed effect. Robust standard errors in parentheses. All dependent variables except Default are in logarithmic form. *** p<0.01, ** p<0.05, * p<0.1. "Short-Run" covers the impact of the program in 2018.

Evaluating the estimation results at variables averages, as discussed in the previous section, we present the impact of an extra 1 million TL loan generated via the CGF program by sector groups in Figure 12. The figure shows that an extra 1 million TL loan generated via the CGF program preserved the most employment in the service sector and the least employment in the wholesale and trade sector. A negative correlation between the cost of preserving employment

and the labor intensity is strongly evident from our results. In contrast, generating one extra TL in sales via the CGF program is the cheapest in the wholesale and trade sector and the most costly in the tourism sector. An extra 1 million TL loan via the CGF program leads to a higher reduction in credit default in construction and manufacturing sectors, 12 percent reduction in the former, and 7.5 percent reduction in the latter, Figure 12b.²²

(b) Credit Default Probability*

Source: Authors' calculation from the CGF, FTR and CR databases.

Notes: In panel (a), the first bar shows the number of preserved employment while the second bar represents the amount of sales generated for receiving 1 million TL of CGF loan for each sector. In panel (b), each bar shows the percentage point change in default rate relative to the mean default rate by receiving 1 million TL of CGF loan.

* We do not find statistically significant estimates for Services and Tourism sectors, hence, we intentionally do not present monetary impact calculations for these sectors.

According to these results, the CGF program was more effective in preserving employment in labor-intensive sectors, particularly the services sector, and generated more sales for sectors serving more to domestic markets, especially the wholesale and trade sectors. By the same token, the lower impact of the CGF support for the sales of firms in the tourism sector may be because most of their sales come from foreign tourists in the form of service exports. Given the significant slowdown in the construction sector in 2016, the CGF program appears to have a significant positive impact on the performance of the CGF supported construction firms, including a large decline in the credit default probability.

²²As the program impact on credit default probability for the firms in services and tourism sectors is statistically insignificant, we excluded these sectors from the Figure.

6.3 Counter-Factual Policy Discussion

As discussed above, the CGF program impact varies significantly across size and sector groups. Utilizing this heterogeneity, we provide a counter-factual analysis to show that substantial efficiency gains can be achieved by reallocating the resources across size and sector groups based on different policy priorities (e.g., preserving employment and generating sales).

The counter-factual policy exercise for the size and sector groups are presented in Tables 9 and 10. In the tables, we provide three main sub-headings: the original CGF program allocation, the scenario allocation, and finally, the percentage change in the dependent variable with the new scenario relative to the original. The original program allocation shows the share and volume distribution of the total CGF backed loan amount in 2017 and 2018 across size and sector groups, as well as the implied employment and sale impact of the program based on the estimates presented above. Under the scenario allocation, we take one percent of the total loans generated via the CGF program from the least cost-effective group and redistribute the funds to the most cost-effective group. Finally, we present the change in the implied employment and sale effects under the scenario allocation relative to the original allocation. To provide an overall impact of the CGF program, we use the official total CGF backed loan volume for 2017 and 2018, 293 billion TL loans. The loan distribution across the size and sector groups comes from the sample utilized in our analysis.

Moreover, we present the counter-factual analysis results regarding the size groups in Table 9, where we take 1 percent of the total CGF loans from large firms (i.e., the least cost-effective group) and redistribute it to medium-size firms (i.e., the most cost-effective group). With the redistribution of only one percent of the total CGF loans (2.93 billion TL loan) from large firms to medium-size firms, without changing the total size of the CGF program, we can generate roughly a 0.74 percent increase in employment and a 1 percent increase in sales relative to the original program design.

		Original	CGF Program			S		Change in

Table 9: Counter-Factual Policy Analysis across Size Groups

Notes: The impact analysis is based on "Short-Run Effect" estimations, which covers the impact of the program in 2018. Bn is billions. The official figure for the total volume of loans generated via the CGF program in 2017 and 2018, 293 Bn TL, is used in the analysis. The original program allocation across the size groups is computed based on the data utilized in the analysis. "a" implies a 1% increase in the CGF program share under the designed scenario. Firm size is based on official KOSGEB definition, as described in Table A5.

Considering sectoral heterogeneity in the cost of preserving an extra employment and gen-

erating an extra sale, we provide two scenarios in Table 10. More specifically, Scenario A focuses on generating more employment, and Scenario B considers generating more sales relative to the original program design. Under Scenario A, we take 1 percent of the total CGF loans from the wholesale and trade sector (i.e., the least cost-effective group in generating employment) and redistribute it to the most cost-effective sector, service sector firms. Our redistribution of only one percent of the total funds originally allocated to wholesale and trade sector (2.93 billion TL) to the service sector firms generates roughly 2 percent more employment; however, the program's total sale impact decreases 0.6 percent relative to the original distribution. Now, we repeat the policy exercise to improve the implied impact of the program on sales under Scenario B, whereby we take 1 percent of the CGF loans from the tourism sector (i.e., the least cost-effective group in generating sales) and redistribute it to the most cost-effective wholesale and trade sector firms in generating sales. Under Scenario B, we can generate 1 percent more sales; however, the program's total employment impact decreases by 0.5 percent relative to the original allocation. By the same token, one can focus on intermediary cases where improving the program's employment and sales impact is feasible, which appears to be feasible by reallocating some of the resources to the manufacturing sector.

Total	1.00	293	772240.62	853.92	1.00	293	768397.29	862.54	-0.498%	1.010%	

Table 10: Counter-Factual Policy Analysis across Sectors

Notes: The impact analysis is based on "Short-Run Effect" estimations, which covers the impact of the program in 2018. Bn is billions. The official figure for the total volume of loans generated via the CGF program in 2017 and 2018, 293 Bn TL, is used in the analysis. The original program allocation across the sector groups is computed based on the data utilized in the analysis. "a" implies a 1% increase in the CGF program share and "b" implies a 1% reduction in the CGF program share under the designed scenario.

Overall, our simple policy exercise indicates that using the heterogeneity in the program impact across the firm size and sector groups, one can re-design the CGF program with different policy priorities (e.g., more employment or sales) which may bring about significant efficiency gains.

7 Further Extensions

In this section, we shift our focus towards different firm assets types, liabilities and exit. We then aggregate our data to province and NACE Rev-2 Classification levels to provide further estimation results on macro implications of the program via re-distributional effects.

7.1 Impact on Other Firm Outcomes

The program's impact on various asset types can potentially differ based on firms' short- and long-run perspectives in managing risks and exploiting growth opportunities, while using the funds. For instance, firms may prefer to respond to uncertainty (the geopolitical shocks in the second half of 2016 in Turkey) by increasing their precautionary funds in liquid form, suggesting a positive relationship between the CGF support and liquid assets. On the contrary, one of the expected outcomes of the CGF program was an increase in inventories. This argument was while many non-CGF firms were negatively affected by the distortions on domestic supply networks and the demand as a result of the increased uncertainty, the CGF supported firms presumably experienced relatively less financial stress, and hence, were able to continue with production even though they may not find appropriate demand for their products. In turn, they would be expected to experience a temporary increase in their inventories.

Similarly, firms may postpone their investments in response to increased uncertainty. However, given that many capital assets are also perceived as collateral and also provide a cushion to macro shocks, such as currency fluctuation²³ especially during times of high uncertainty, some of the CGF supported firms might have still considered investing in these assets. Our results on tangible assets, containing land and buildings, machinery and equipment, and vehicles, shed light on these on these diverging incentives. Finally, the CGF program's impact on firms' intangible capital (i.e., patents, R&D activities) and indebtedness (e.g., the differential between asset and liability growth) is particularly crucial to provide a perspective on the long-term implications of the CGF program. The former tells us about future firm productivity and growth potential, while the latter is informative about firms' future financial sustainability.

As a compliment to our earlier estimates on credit default probability, the program presumably has also reduced firm exits by reducing the financial stress on CGF supported firms. To test this argument, we assign one to exiting firms (i.e., not reporting balance sheet) and zero for others in our base sample, we estimate the program impact on firm exit.²⁴

²³Most of the machinery and equipment type capital, and vehicles are imported from abroad in Turkey, and thus, their prices are pegged to foreign currency prices.

²⁴Various definitions of firms exit, e.g., filing bankruptcy, balance sheet reporting status, the decline in employment or sales to zero, etc., are used in the literature given that identifying year-on-year firm exit is a difficult one. We define year-on-year exit based on firms' financial statement reporting status for tax purposes, as the Turkish Tax Code requires legal firms to report balance sheets as long as they legally remain in operation, and thus, it is legitimate to interpret not reporting balance sheet as firm exit.

Thereby, we estimate our main model for different asset types, liabilities and firm exit and present the results with the baseline specifications only for brevity in Table 11.

Notes: The table presents the regression results for the short-term effect of the CGF program on other firm outcomes in a binary setting. Each column includes pair fixed effect. Robust standard errors in parentheses. All dependent variables except exit are in logarithmic form. For estimating column 10, we assign one to exiting firms (i.e., not reporting balance sheet) and zero for others in our base sample in 2017 and 2018. "Very Short-Run" covers the impact of the program only in 2017, while "Short-Run" covers the impact of the program in 2018. *** p<0.01, ** p<0.05, * p<0.1.

According to the results, the CGF supported firms increased their total assets by 24 percent in the very short-run that magnitude is similar in the short-run. Liquid assets are also affected positively by the program, as CGF supported firms increased their liquid assets by 34 percent more than their pairs in the very short-run, while the effect drops to half in the short-run. The CGF supported firms on average experienced a 44 percent increase in their inventories relative to their pairs in the very short-run. However, the increase in inventories was temporary, as the estimated coefficient falls in the short-run specification. The increase in both liquid assets and inventories appears to be temporary, given some of the effects diminish in the short-run.

The program's impact is estimated to be positive for the tangible assets, whereby the CGF supported firms, on average, increased their tangible assets about 29 percent more than their pairs in the very short-run. The effect remains to be the same in the short-run. Among the constituting asset types of tangible assets, the CGF program generally has a positive impact on all three classes. However, the size of the impact across asset types, as well as the very short-run and the short-run attributions differ significantly. More specifically, the CGF supported firms on average invested 34 percent more in land and buildings, 22 percent more in machinery and equipment, and 41 percent more in vehicles than their pairs in the very short-run. In the short-run, the impact on land and buildings remains mostly similar to that of the impact in the very short-run attributions to 31 percent. Vehicle purchases are higher in the very short-run among other asset types that significantly decreases in the short-run. The impact on intangible assets and total liabilities are 23 percent and 36 percent in the very short-run those estimates remain in similar magnitude in the short-run. The CGF program appears to have reduced firm exit probability in the short-run, where, the CGF supported supported firms, on average, experienced

a 4.3 percentage point less exit in the short-run relative to the control group.

We present their economic significance of the estimates for an extra 1 million TL CGF backed loan in Figure 13. According to the figure, the program impact on tangible assets and inventories are sizable, while the minimal impact is observed in intangible assets. On the contrary, the program impact on total liabilities is much larger than the total assets among the CGF supported firms, which in turn implies an overall increase in firm indebtedness.²⁵

Figure 13: Average Monetary Impact of CGF Supported Loans (per 1 million TL of CGF loan), Other Firm Outcomes

(b) Intangible Assets, Total Liabilities and Assets

Source: Authors' calculations.

Notes: The figures present the average monetary impacts of receiving 1 million TL of CGF loan. Mach. & Eq. represents machinery and equipment while Land & Build. represents the land and buildings.

The program impact on fixed capital (e.g., tangible assets) seems to be sizable, yet only a small proportion of this investment went into productive capital, such as machinery and equipment. Additionally, its impact on long-term capital, such as intangible assets, appears to be weak, which is perhaps not too surprising given that the CGF program was initially designed to improve firm resilience to the temporary negative shocks in the domestic economy. However, our results also indicate an increase in firm indebtedness, where liabilities grew faster than assets with the CGF program. This high indebtedness can threaten firms' financial health in the long-run, especially given the weak impact of the program on long-term firm perspectives. Such risks may be particularly acute for certain types of firms. Given our results in Section 6.1, for instance, especially the CGF supported micro-firms appear to experience a significant increase in credit default probability in 2018.

²⁵As an alternative indebtedness measure, we also re-estimated our model with leverage being the dependent variable. The results are qualitatively similar, where the CGF supported firms on average experienced a larger increase in total leverage relative to their matched pairs.

7.2 Macro Implications

We have talked little about the re-distributional effects of the CGF program until now. This is to say that a new hire of a firm (the CGF supported firm) may be an employee or another firm's layoff (control group). In other words, we may observe, for instance, an increase in employment, motivated by the CGF program at the firm- level; however, because of the possibility that the new hire may not come from the unemployment pool, rather from other firms, total employment may not increase in the country. To capture this, we estimated our main model at sector-province level to check if the positive and statistically significant impact of the CGF program prevails after accounting for general equilibrium effects (GE). In identifying the GE effects, we assume that employees may frequently switch between firms, while this switch is less frequent across the broadly defined NACE Rev-2 classification level sectors in the same province or across provinces for a given sector.²⁶

The estimation results for employment and sales are presented in Table 12. The results show that a one percent increase in CGF program at the sector–province-level increases employment by 0.2 percent and sales by 3 percent. This is in line with our earlier expectations, where the impact is much lower at the macro-level due to the program's re-distributional impact. Nevertheless, the coefficient estimates remain statistically significant and economically consistent across different specifications, and hence, further reinforce the positive impact of the CGF program at the macro level.

"Short-Run" impact model is presented at province – sector (NACE Rev-2 Classification) level. All the models contain, provinceXsector fixed effects.

8 Robustness Checks

We have presented various results beside our baseline specification throughout the discussion above, which already reinforces the robustness of our results to several checks, including controlling for several fixed effects, firm fixed effects, NACE Rev. 2 Classification level sector-time

²⁶Further aggregations of the sample, to only sector or province level, significantly reduce the number of observations and, thus, the estimates' reliability.

and province-time fixed effects, additional controls (non-CGF loans) and estimations with different sub-samples. Therefore, we focus on other potential concerns in this section.

Our main sample, used in the baseline analysis, requires firm survival both in the matching/control and treatment years. In other words, firms that did not report balance sheets are "treated" as exiters in our base sample (*Sample* 1). In the discussion above, we have already stated that the share of exiting firms is small. However, to remove this restriction from our estimates, we impute zeros to the employment and sales of exiting firms in 2017 and in 2018 that form our new sample, *Sample 1 with filling*. This is a well-applied method in the empirical literature (e.g., Brown and Earle, 2017). However, we do not apply the same idea to credit default, where assuming credit default for an exiting firm (i.e., assigning one for the credit default of exiting firms) may actually not always be the case in reality, as firms may not have outstanding credit or had already liquidated the outstanding credit balance through the bankruptcy process. By the same token, we construct another sample (*Sample 2*), where we add firms that were around only in 2016 (not in 2015) to our matching methodology. As done for *Sample 1*, we present our main results for *Sample 2* with a requirement on survival in 2017 and in 2018 (i.e., *Sample 2 without filling*) and also, without a requirement on survival (i.e., *Sample 2 with filling*).

Firms in the energy sector usually tend to be large and use FX denominated credits to finance large scale investment projects, given the very nature of the sector that highly relies on imported capital goods.²⁷ As a result, energy sector firms coverage of the CGF program is relatively small. On the contrary, firms in the agriculture and mining sector, especially the agriculture, generally tend to be micro family firms, whose coverage is limited in our sample given the exclusion of unincorporated businesses from the analysis. Overall the CGF program coverage of these sectors is only 3 percent, and thus, excluding these sectors from the analysis should not affect our results. While sector-specific characteristics are mostly captured by the sector-specific fixed effects in our baseline specification, we still find it useful to note that our main results are robust to the exclusion of firms in these sectors from the analysis.

For brevity, we discuss only the robustness of our estimates from the binary treatment specification in this section. However, we should note that the continuous treatment results are very similar.²⁸

Robustness Test 1: Sample 1 with Filling

Table A2 presents the results from the binary treatment with *Sample 1 with filling*. According to the results, the main dependent variables' estimated effects are slightly higher than those without the imputation; however, the significance levels and signs do not change in all specifications. Given our credit default results, the CGF program has a positive impact on firm survival. Thereby, the exiting firms tend to be the control firms in the matched pairs, as the CGF supported firms tend to

²⁷See Footnote 9.

²⁸These results are available upon request.

default less and survive more. In turn, putting the exiting firms back to the estimation with zero imputations for their employment and sales seems to slightly increase the CGF program's impact on employment and sales. The statistical significance and the sign of the estimates, however, are preserved across all the specifications.

Robustness Test 2: Sample 2 without Filling

Table A3 shows the results for the binary treatment specification with *Sample 2 without filling*. The number of the matched CGF firms with controls increases to 67,446 in this sample, as we no longer require firms to exist in both years, 2016 and 2015, to be included in the matching. The estimated treatment effects for all variables do not change across all specifications, suggesting that our baseline results are robust to different sample selections.

Robustness Test 3: Sample 2 with Filling

Table A4 displays the results for the binary treatment specification with *Sample 2 with filling*. The results for the estimated treatment effects for all variables do not change across all specifications, suggesting that our baseline results are robust to imputing zeros for the exiting firms in *Sample 2*.

Robustness Test 4: Excluding Firms in Energy, Agriculture and Mining Sectors

Excluding the firms in energy, agriculture and mining sectors do not change the results for the binary treatment specification with *original sample*. As the results are very similar to the original ones, we do not report them for brevity.²⁹

9 Conclusions

Using novel administrative databases, this paper evaluates one of the biggest CGF programs in the world implemented recently in Turkey. We first matched our sample of the CGF supported firms with their close pairs via coarsened and exact matching method and then implemented a difference-in-difference estimation to evaluate the program's impact on the performance of treated firms relative to their matched pairs. Our results show that the CGF supported firms, on average, preserved 17 percent more employment, generated 70 percent more sales, and experienced 0.6 percentage point less credit default than their matched pairs in 2018. Evaluating these estimates at their sample averages implies that an extra 1 million TL loan generated via the CGF program preserved roughly 2.7 more employment, generated about 3 million more sales,

²⁹Results are available upon request.

and reduced the average credit default probability by nearly 6.5 percent in 2018. Considering the official figure, a total of 293 billion TL loan volume generated via the CGF program in 2017 and 2018, and assuming linear applicability of our estimates to this figure, the implied overall program impact of the program on the Turkish economy in 2018 was roughly 794 thousands more employment and 879 billion TL more in sales.

Our results identify that the program impact is the highest among SMEs, where the cost of preserving one more unit of employment, sales, and reducing credit defaults on average is the cheapest. On the contrary, the results for cross-sector groups show that the cost of preserving one more employment is cheaper in more labor-intensive sectors (e.g., services), and the cost of generating one extra TL sales is cheaper in sectors that serve more to the domestic economy (e.g., wholesale and trade). Exploiting the program impact heterogeneity across size and sector groups, we provide counter-factual policy analysis. The results from the counter-factual analysis indicate that moving only one percent of the TL loans generated via the CGF program from the least cost-efficient size group (e.g., large size) to the most cost-effective size group (e.g., medium size) increases total employment and sales impact of the program roughly one percent. Crosssectoral redesign of the program is less straight forward. Moving one percent of the total CGF loans from the least cost-effective (and the least labor-intensive) sector (e.g., wholesale and trade) to the most cost-effective (and the most labor-intensive) sector (i.e., service sector) increases the employment impact of the program for about 2 percent, although decreases its sales impact. Similarly, redistributing one percent of the total CGF loans from the tourism sector (serving least to the domestic sector) to the wholesale and trade sector increases the program's sales impact by about 1 percent, although decreases the employment impact of the program. The manufacturing sector appears to provide an intermediate case, where both employment and sales impact of the program can be improved by redesigning the program.

The program's impact on assets that can stimulate long-run firm growth via productivity enhancements seems relatively weak. This is perhaps not surprising given the aim of the CGF program in 2017 was to minimize the negative impact of the geopolitical developments on domestic real sector firms. Thereby, the CGF program seems to achieve its initial aim by restoring firm strength in the short-run via preserving employment and sales, although it contributes less to firms' long-term growth prospects. In this regard, the CGF type short-term-focused programs should not be considered as an alternative to the programs aiming to simulate productive capital investment. Our results also highlight an increase in firm indebtedness as a result of the CGF program. We observe a more acute increase in firm liabilities than assets. This finding coupled with the results that the CGF program's mitigating impact on credit default probability fades over time, implying credit risks may increase in the long-run. One way to tackle this issue is to closely monitor firm indebtedness and ensure the necessary debt management practices are being implemented. In this regard, the micro firms should be closely monitored and mentored to sustain their financial resilience in the long-run.

Due to data restrictions, we had to exclude unincorporated businesses from the analysis.

Although their size is relatively small both in the CGF program and in the Turkish economy, they may be especially important for our risk analysis and firm credit default results. Mainly because micro firms are usually more vulnerable to shocks and, thus, riskier. However, we cannot provide a direct analysis on this concern, which remains a caveat for our results. Secondly, our analysis covers one full year (2018) in the post-CGF program and the year of 2017, which contains both the program implementation and impact. Therefore, the observed positive impacts along with the negative ones may amplify over time. Lastly, our results do not account for firm-to-firm spillovers. However, we know that fiscal policy multiplies through the interactions of agents in an economy. That suggests some of our results may amplify once the firm-to-firm interactions are considered.

This study evaluates the first order firm-level impact of the CGF program in the short-run. However, further research on the micro, macro, and distributional implications of the program is deemed necessary to identify the overall program impact. Presumably, an extensive program of this size can have implications for the banking sector and the financial network, while at the macro level, the potential impact on inflation, economic growth, financial stability, and productivity are also worth noting. These considerations will be further explored in our future research agenda.

Table A1: Summary Statistics for Evaluating the Monetary Impact of CGF Program

Notes: Each column presents the mean values of the related variable for CGF supported firms in each group for year 2016 and Short-Run equation. "Short-Run" equation covers the impact of the program in 2018.

* We exclude the firms with at least one default event prior to receiving CGF loan in 2017, hence, we have a smaller sample for the regressions with default outcome, though the total number of such firms is not much. Moreover, in order to make ex-post estimations in terms of firm default, we present the mean default rate for CGF and non-CGF firms in 2018 different than the other variables.

Notes: Columns 3-6-9 include firm fixed effect instead of pair fixed effect. The sector-time and province-time fixed effects are included in all specifications to control for overtime industry and province specific shifts. Robust standard errors in parentheses. All dependent variables except Exit are in logarithmic form. *** p<0.01, ** p<0.05, * p<0.1. "Very Short-Run" covers the impact of the program only in 2017, while "Short-Run" covers the impact of the program in 2018.

Table A4: Robustness Test 3 (Sample 2 with Filling): The Effect of the CGF Program on Firm Performance, Binary Treatment

Notes: Columns 3 and 6 include firm fixed effect instead of pair fixed effect. The sector-time and province-time fixed effects are included in all specifications to control for overtime industry and province specific shifts. Robust standard errors in parentheses. All dependent variables are in logarithmic form. *** p<0.01, ** p<0.05, * p<0.1. "Short-Run" covers the impact of the program in 2018.

Table A5: SME Classification

Criteria	Micro-Sized Enterprise	Small-Sized Enterprise	Medium-Sized Enterprise
Number of Employees	< 10	< 50	< 250
Annual Net Sales Income	< 3 Million TL	< 25 Million TL	< 125 Million TL
Annual Financial Balance Sheet	< 3 Million TL	< 25 Million TL	< 125 Million TL
